Operator taking courses or horizontal angles with BRUNTON'S PAT. POCKET MINE TRANSIT.
If you wished to find the angle between two points below the horizontal with a sighting compass or an ordinary transit, you would first have to set up your tripod or staff and then level up your instrument. All this takes time.
If you only wanted to get the angle within a degree or so, you could take a BRUNTON TRANSIT, and, holding it in the position shown, take your readings in less time than you can place any other instrument. Send for descriptive catalogue B to

No. 044 BUTTON BALANCE. Sensibility 1-100 milligramme. If you are in the market for the very best balance obtainable at a moderate price, write us for particulars about the No. 044. You will be surprised to find how cheaply it can be purchased for cash. While we cannot recommend this balance for fine gold work, a great many assayers are using it for such successfully. Send for illustrated catalogue A, for complete description and prices, to

THE IDEAL CONVEYOR BELT

Is the one that will carry stone, ore, coal, wet or dry material, holding buckets firmly and securely; will stand all kinds of exposure, and resist the heaviest strains during a long period of service. This is wha the **LEVIATHAN BELT** has done, and we quote the following from a letter from the New York Steam Co.:

"We have used Leviathan Belting for four years, up to 24-inch by 8-ply, elevating and conveying coal. Some of the Belting is outside, exposed to freezing weather; some in a steam bath. In both conditions the results have been very gratifying, over 500 tons having been handled in ten hours time."

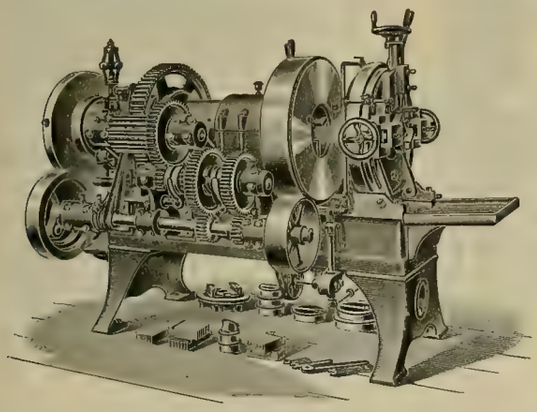
Sole Pacific Coast Agents and Builders of the Celebrated

WILFLEY CONCENTRATOR.

The Wilfley Table is fully covered by U. S. patents Nos. 580,338 and 590,675. Infringements will be prosecuted to the full extent of the law.

PRICE, $450, F. O. B., San Francisco.



One of these machines will take the place of two or three belt concentrators of any style and do very much better work.

Some Practical Reasons Why the Wilfley Concentrator Should Be Used in Gold Mills:

1. It will successfully handle three or four times more material than any belt Concentrator made, without exception.
2. It will save more sulphurets in proportion while so doing, and catch any float gold, amalgam or quicksilver which may escape from mortars or plates.
3. It will make cleaner and much more valuable concentrates, thus saving useless expense for transporting valueless material, as also extra cost for treatment.
4. It requires little or no attention when once adjusted and no expert is required to either adjust or run the machine.
5. It will save much expense in power and room, and the first cost of a mill requiring concentrators.
6. It has no expensive belts to crack and wear out, nor complicated machinery to keep in repair.
7. It is the only sensible plan of concentration, as any kind of material can be worked, which is not true of any style of belt machine.

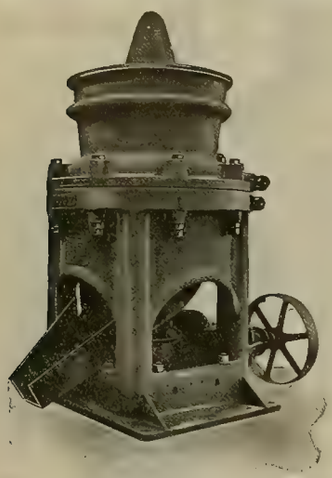
Inventors on the Pacific Coast will find it greatly to their advantage to consult this old experienced first-class agency. We have able and trustworthy associates and agents in Washington and the capital cities of the principal nations of the world. In connection with our scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of patents already granted, for the purpose of determining the patentability of inventions brought before us, enables us to give advice which will save inventors the expense of applying for patents upon inventions which are not new. Circulars and advice sent free on receipt of postage. Address **DEWEY, STRONG & CO., Patent Agents, 330 Market St., San Francisco, Cal.**



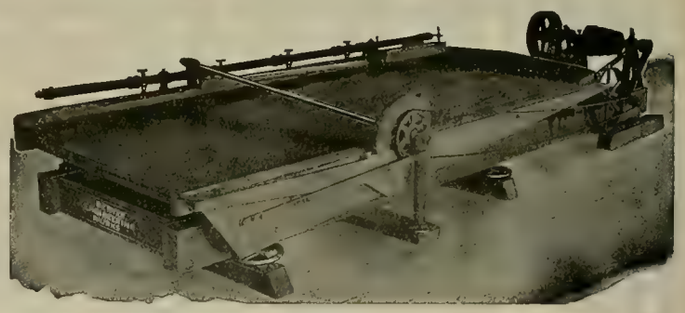
THE RISDON HAMMERED SHOES AND DIES

Manufactured from the best quality of projectile steel—which is stronger and tougher than any heretofore used—the best shoe and die ever made. Will crush more ore per pound of steel than any other. Will not chip or cup and will outcrush any other made. Wear smooth and true with hardly any perceptible decrease in their size, and those who use them say, "We never had shoes and dies wear so long." Send for circulars and dimension blanks to

THE RISDON IRON WORKS, SAN FRANCISCO.

GATES FINE CRUSHER.

The result of ten years' solid work. Success at last. What we wanted, and the public demanded, was a Gates Gyratory Rock and Ore Breaker (always adjustable and indestructible) so modified in design as to make one-half-inch product from three-inch sizes, rapidly and cheaply. The H Fine Crusher will do this work. It takes the place of expensive big rolls and often prepares ore, without further crushing, fine enough for coarse concentration or cyaniding. In any event, it is the greatest and best intermediate machine between the coarse breaker and the pulverizer.



Ask for No. 1 Catalogue. :: GATES IRON WORKS, Dept. UU, 650 Elston Ave., CHICAGO.

THE : CAMMETT : CONCENTRATOR.

Designed with some Regard for the Laws of Concentration.

The perfect vanner motion given to the pulp by our head motion, together with the freedom from "jumping" resulting from the special rigid guides used, explains why the Cammett riffles never "pack," and why the table has such a great capacity when handling slimes. : : : : : : : : : : : : : : : : :

The continuous grooves and riffles extending from end to end of the table maintains the greatest possible margin of safety between the concentrates discharge and the tailings. : : : : : :

Assessment Notices.

SAILOR CONSOLIDATED MINING COMPANY.—Location of principal place of business, San Francisco, California; location of works, Placer County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 12th day of July, 1899, an assessment (No. 1) of eleven cents (11c) per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the secretary, at the office of the company, 318 Front street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 21st day of August, 1899, will be delinquent and advertised for sale at public auction, and, unless payment is made before, will be sold on MONDAY, the 18th day of September, 1899, to pay the delinquent assessment, together with the costs of advertising and expenses of sale.

By order of the Board of Directors.
M. C. LUND, Secretary.
Office—318 Front street, San Francisco, California.

MARGUERITE GOLD MINING AND MILLING Company.—Location of principal place of business, San Francisco, California; location of works, Auburn, Placer County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 19th day of July, 1899, an assessment (No. 14) of 10 cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the secretary, at the office of the company, 237 12th street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 28th day of August, 1899, will be delinquent and advertised for sale at public auction; and unless payment is made before, will be sold on MONDAY, the 25th day of September, 1899, to pay the delinquent assessment, together with the costs of advertising and expenses of sale.

By order of the Board of Directors.
F. METTMANN, Secretary.
Office—237 12th street, San Francisco, California.
The Secretary will also receive payments from 12 to 5 P. M. at his business office, 225 Sansome street.

CENTRAL EUREKA MINING COMPANY.—Location of principal place of business, San Francisco, California; location of works, Sutter Creek, Amador County, California.

Notice is hereby given that at a meeting of the Board of Directors, held on the 25th day of July, 1899, an assessment (No. 13) of three cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin to the secretary, at the office of the company, room 9, 320 Sansome street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 1st day of September, 1899, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on MONDAY, the 25th day of September, 1899, to pay the delinquent assessment, together with the costs of advertising and expenses of sale.

By order of the Board of Directors.
WM. A. M. VAN BOKKELEN, Secretary.
Office—Room 9, 320 Sansome street, San Francisco, California.

SIERRA NEVADA SILVER MINING COMPANY.—Location of principal place of business, San Francisco, California; location of works, Virginia Mining District, Storey County, State of Nevada.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 15th day of July, 1899, an assessment (No. 116) of 15 cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the secretary, at the office of the company, room 14, Nevada Block, No. 309 Montgomery street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on FRIDAY, the 18th day of August, 1899, will be delinquent and advertised for sale at public auction; and unless payment is made before, will be sold on THURSDAY, the 7th day of September, 1899, to pay the delinquent assessment, together with the costs of advertising and expenses of sale.

By order of the Board of Directors.
E. L. PARKER, Secretary.
Office—Room 14, Nevada Block, No. 309 Montgomery street, San Francisco, California.

MARIPOSA COMMERCIAL AND MINING COMPANY.—Location of principal place of business, San Francisco, California; location of works, Mariposa County, California.

Notice is hereby given that, at a meeting of the Board of Directors, held on the 28th day of July, 1899, an assessment (No. 12) of ten ($10) dollars per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the secretary, at the office of the company, 320 Sansome street, room 24, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 5th day of September, 1899, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on FRIDAY, the 29th day of September, 1899, to pay the delinquent assessment, together with the costs of advertising and expenses of sale.

By order of the Board of Directors.
JOSEPH H. MOOSER, Secretary.
Office—320 Sansome street, room 24, San Francisco, California.

ORLEANS MINING COMPANY.—Location of principal place of business, San Francisco, California; location of works, Grass Valley, Nevada County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 31st day of July, 1899, an assessment (No. 9, new series) of five (5c) cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the secretary, at the office of the company, 324 Pine St., San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 8th day of September, 1899, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on TUESDAY, the 3rd day of October, 1899, to pay the delinquent assessment, together with the costs of advertising and expenses of sale.

By order of the Board of Directors.
GEO. P. THURSTON, Secretary.
Office—Room 10, 324 Pine St., San Francisco, California.

NATIONAL CONS. MINING COMPANY.—Location of principal place of business, San Francisco, California; location of works, Rich Gulch, Shasta County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 9th day of August, 1899, an assessment (No. 8) of ten (10) cents per share, was levied upon the capital stock of the corporation, payable immediately in United States gold coin to the secretary, at the office of the company, No. 773 Mission St., San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 18th day of September, 1899, shall be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on WEDNESDAY, the 11th day of October, 1899, to pay the delinquent assessment, together with the costs of advertising and expenses of sale.

By order of the Board of Directors.
GEO. W. FLEISSNER, Secretary.
Office—773 Mission St., San Francisco, California.
Office hours from 1 to 3 P. M.

EUREKA CONSOLIDATED DRIFT MINING COMPANY.—Location of principal place of business, San Francisco, California; location of works, Forest Hill Divide, Placer County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 10th day of August, 1899, an assessment (No. 20) of one-half cent per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the secretary, at the office of the company, No. 1209 Claus Spreckels building, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 12th day of September, 1899, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on SATURDAY, the 30th day of September, 1899, to pay the delinquent assessment, together with the costs of advertising and expenses of sale.

By order of the Board of Directors
J. J. CRAWFORD, Secretary.
Office—1209-11 Claus Spreckels building, San Francisco, California.

THE BROWNELL "PATENT LIP" FLANGE FRUE VANNER BELTS.

It has taken years of ceaseless testing and experimenting to produce the superior belt which we now offer, with elastic flanges and pliable body reinforced with specially woven duck. Every belt is manufactured by experienced workmen, and carefully tested on machines especially built for that purpose; consequently we are to-day manufacturing the best belts that mechanical ingenuity, combined with honesty of construction, can possibly produce.

ORIGINAL EMPIRE MILL & MINING COMPANY,
GRASS VALLEY, NEVADA CO., CAL., Feb. 20, 1897.

JAS. S. BROWNELL, ESQ., San Francisco, Cal.—DEAR SIR: The Brownell Patent Lip flange belt for ore concentrators, which I bought of you nearly two years ago, has been in constant use and is in good order and gives us perfect satisfaction. We have several other kinds of belts in the mill, and your belt and flange I consider the best of all. Yours respectfully, ROBT. WALKER, Superintendent.

ROANOKE MINING COMPANY,
MOKELUMNE HILL, March 4, 1897.

MR. JAS. S. BROWNELL, 132 Market St., San Francisco, Cal.—DEAR SIR: We have in our 20-stamp mill at this place five Frue vanners; three of these are equipped with the Patent Lip flange belt and two with the plain flange belt. We certainly consider the former a great improvement on the latter. They will certainly wear much longer, as cracking now seems out of the question. Any one purchasing the Frue vanning machine should see that it is equipped with the Patent Lip flange belt. Very truly yours, ROANOKE MINING COMPANY.
Per G. M. WILDE, Acting Superintendent.

AND PACIFIC ELECTRICAL REVIEW.

No. 2041.—VOLUME LXXIX. Number 8. SAN FRANCISCO, SATURDAY, AUGUST 19, 1899. THREE DOLLARS PER ANNUM. Single Copies, Ten Cents.

A Large Electric Motor.

The Sperry Mills, at Stockton, Cal., are installing what is announced as the largest electric motor in California. The motor stands over 8 feet in height; the armature is 6 feet in diameter. The Westinghouse Electric & Manufacturing Company especially built for the Sperry Mills one of their type "C" induction motors, rated nominally at 400 H. P., 2200 volts, but capable of carrying 500 H. P. An illustration of this motor is given in Fig. 1. In the San Joaquin valley numbers of these motors, ranging from 5 to 50 H. P., are employed for operating pumps. Gold dredging companies on the Yuba and Feather rivers employ several motors for operating gold dredgers and mining apparatus. In the Cripple Creek, Colo., gold mining district hundreds of such motors are in use for driving mine hoists, pumps, concentrators and rock crushers. In the Eastern States there are many industries using powers, in which this type of motor has been introduced with great advantage. They are virtually automatic and can be run by an inexperienced workman without danger. They are sparkless, and, in consequence, the United States Government has adopted them for the powder mills at the Indian Head proving grounds on the Potomac, and elsewhere. The motor has two main elements—the primary, which is directly magnetized by the current supplied from the circuits; and the secondary, in which low potential currents are induced by the action of the primary. The windings of the primary are so arranged that when supplied with alternating currents differing in phase, a rotary magnetic field is produced. This field acts upon the secondary winding and induces currents therein. Rotation is produced by the action between the secondary currents and the rotating field of the primary. From a mechanical standpoint, this motor is reduced to the smallest possible elements, a stationary part permanently connected to the main circuits, and a rotating part having no electrical connection with any other. The only parts that can wear are the shaft and journal boxes. This simplicity enables the motor to operate for long periods of time with a minimum of attention. The large motor supplied to the Sperry Mills at Stockton, Cal., has a hollow, cylindrical frame of cast iron, in which the primary is mounted. This frame for holding the primary is of two parts, which are separated horizontally.

The primary element, shown in Fig. 2, consists of a hollow cylinder built up of laminated rings of sheet steel, mounted on the inside to receive the conductors. In motors of a large size, such as supplied to the Sperry Company, the rings are not continuous, but are made up of segments, which are dovetailed and are fitted into corresponding slots in a hollow, cylindrical shell of cast iron. This shell is held in the cast iron frame of the motor. The conductors are machine-wound coils of wire, thoroughly insulated before being slipped into the slots of the primary iron core.

The secondary of this machine is illustrated in Fig. 3, and is built up of laminated steel discs, made of a high grade of metal, mounted upon an open spider, and carrying in slots around the periphery the rectangular copper bars of the winding. The whole secondary is simple, rigid and durable. The conductors of the secondary are all purposely short-circuited, hence no accidental short circuit can occur to cause injury to the windings. The construction is practically indestructible from heating, raising of coils or mechanical injury in handling. The advantage of so simple and substantial a construction without moving contacts and switching device has led to a wide use of this induction motor. The motor herewith illustrated by engravings specially prepared for this paper will be operated by electric power furnished from the Blue Lakes generating plant of Amador Co., Cal.

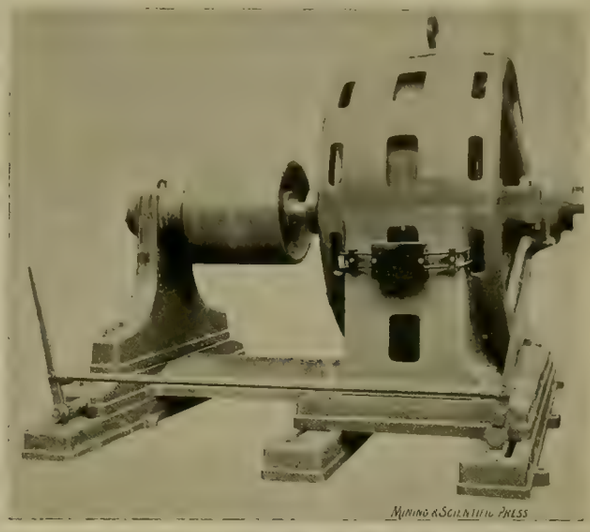

FIG. 1.—INDUCTION MOTOR, 400 H. P., SPERRY MILLS, STOCKTON, CAL.

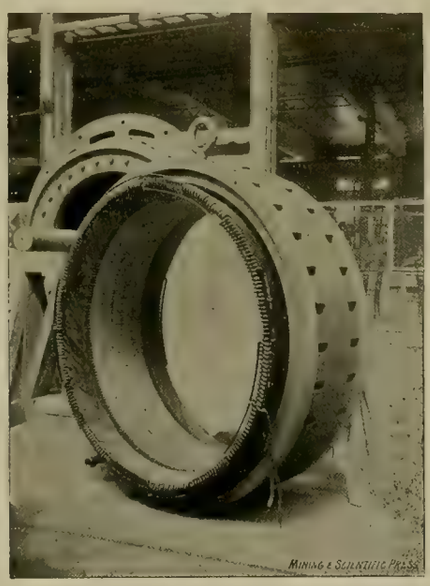

FIG. 2.—STATIONARY PRIMARY WESTINGHOUSE TYPE "C" INDUCTION MOTOR, 400 H. P., SPERRY MILLS, STOCKTON, CAL.

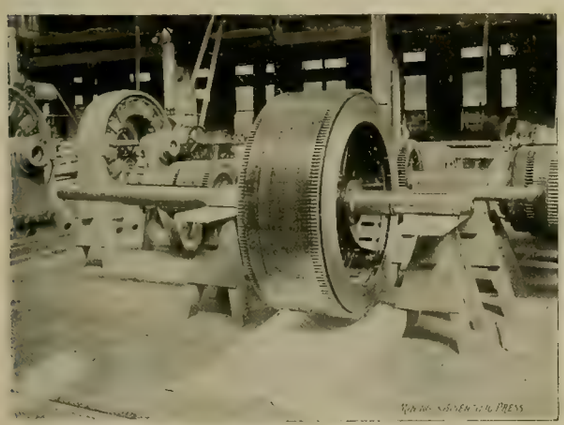

FIG. 3.—ROTATING SECONDARY OF WESTINGHOUSE TYPE "C" INDUCTION MOTOR, 400 H. P., SPERRY MILLS, STOCKTON, CAL.

AT the Hodbarrow mines in the south of Cumberland, England, an engineering project is being promoted to construct an embankment about the mine, calculated to keep the sea out of the workings of one of the principal mines. Ten years ago nearly $1,000,000 was spent in this manner and the enterprise proving successful it is now proposed to go farther seaward on a more ambitious scheme. The new wall will be in the form of an embankment with a puddled trench, with rough squares of concrete tumbled down the bank as a breakwater for the sea. This new embankment will be 6750 yards long and will enclose 170 acres of land, under which the new extension of the mine will be worked. Ore has been proved to exist in vast deposits under this area. The cost of the proposed scheme will probably be from £400,000 to £500,000, but is said to be well worth the enterprise, as Hodbarrow ore is the best hematite in England.

The Contract System.

The contract system of operating mines in British Columbia, introduced two months ago, at that time considered a dignified compromise between mine owners and miners, and which was said to give satisfaction to both sides of the eight-hour day controversy, is not working smoothly, for the reason, apparently, that some of the miners took contracts at figures too low to make it possible to make $3.50 per shift. The Rossland Miners' Union has passed a resolution to the effect that no union miner shall work on contract in that camp, and at Silverton the Miners' Union has demanded that managers of the Mine Owners' Association give written promises to pay no less than $3.50 per day on contract work. This the mine managers have refused to do. A miner takes a contract at a price which in his judgment will return him at least a full day's pay, and as on contract work men usually work harder, they expect to make more than the regular day's wages. If his judgment has been at fault, he refuses to take another contract at a similar price. The trouble in British Columbia, however, is due to the fact that the miners expect the eight-hour day at the same wages formerly paid for ten hours' work. The contract system, it was thought, would find a way to obviate further unpleasantness, and doubtless had British Columbia miners been able to make $3.50 or more in eight hours while on contract there would have been no further trouble, but failing in this they now demand that $3.50 per day be insured them.

IN California there is no such thing as "non-assessable stock" in a corporation. A California corporation is given power by positive statute to levy necessary assessments, and no power exists in a corporation to waive such legal rights.

TIN continues at a high price, due wholly to an increasing demand with a decreasing production. There is no syndicate buying up all the visible supply as in 1887. Unless the known mines can increase their output and new mines be successfully opened the metal is likely to go several points higher.

EVERYWHERE—except in the mining districts—there is a cry for "more men." Whether it is railroad work in Pennsylvania or California, foundry requirements in Ohio or Colorado, harvesting in Minnesota or Oregon, the present demand for labor is greater than the available supply. This condition of affairs does not obtain in the mining world, which is governed by rules and affected by conditions in some respects dissimilar from other branches of productive industry.

THE Washington, D. C., Commissioner of Patents has made a new ruling regarding applications for patents for machines or processes. Formerly an inventor was entitled to include in the one application claims for the machine or process and the resultant product. The new rule says: "A machine, a process, and a product are separate and independent inventions, and claims for each must be presented in a separate application." This necessitates filing two applications in a process case involving the steps for producing a certain result and the obtained product.

IRON and steel are still in great and increasing demand, and the mines have not yet been able to output more rapidly than the market requires. The continued upward trend of prices for raw material is beginning to affect all branches of manufactures of iron and steel. Machinery for mining purposes, because of its great weight, was the first to feel the effect of the high prices, and now other machinery of lighter kinds is advancing in price. That the prices will soon go to a lower figure there is little hope for this year, as it is now expected that the output will fall short of the estimate. Pig iron is not being produced as fast as consumed and a great deal of old machinery is going to the foundries to be recast and manufactured into modern forms.

American Institute of Mining Engineers.

Beginning September 25th, the seventy-seventh meeting of the American Institute of Mining Engineers will be held in San Francisco.

A banquet will be given to the Institute by the merchants and manufacturers of San Francisco, and receptions will be given at other places in the State. Following is the official programme furnished by Secretary Raymond:

"The special train will leave Chicago by the Chicago & Northwestern Railroad at 5:30 o'clock P. M., on Saturday, September 16th. If a sufficient number of persons, who have secured their places in the special train from Chicago and who desire to go together from New York City, will promptly notify Theodore Dwight, at the office of the secretary, arrangements will be made to have one or more special cars attached to the 1 P. M. New York Central train of Sept. 15th. Railroad and sleeper fares to Chicago are not included in the excursion rate of $225 already published; but a considerably reduced excursion rate to Chicago and return can be secured for a party of sufficient size. Particulars on this point and all changes of schedule or other matters of interest to the excursionists will be furnished by a personal letter to all those who have secured places in the special train.

From the responses already received, it is now clear that the special excursion will comprise a sufficiently large number of members to insure its interest and success, while, on the other hand, it will be possible to accommodate a considerable number of ladies and guests accompanying members. Great care has been taken in the selection of cars, porters, stewards, ladies' maids and cooks for the special train, insuring complete comfort and luxury for the party. The restriction announced in Circular No. 3 giving to members only the first opportunity of securing places in the special train has been rescinded, and applications will be received for guests accompanying members, up to the limit of the accommodation available. First come, first served. A considerable number of members have already applied for places for ladies accompanying them, and it is certain that many ladies will be in the party. Further applications should be made at once to Mr. Dwight, and the requisite advance of $50 for each person should accompany the application. The names of all persons should be given, and it should be stated whether they will go from New York or join the special train at Chicago, or en route.

After August 15th it will be necessary to deposit with each application the whole sum of $225 for the round trip from Chicago. But of this deposit $175 will be returned, if the parties notify this office by September 10th of their inability to go; of the remaining $50 the whole or part will be, in such cases, returned subsequently, as may be practicable.

If the accommodations thus set free by the failure of the original depositor to use them can be sold, for whole or part of the route, to others, the amount returnable will be correspondingly greater, amounting, possibly, to the whole. But as to this no guaranty can be given.

For the benefit of members not acquainted with the climatic conditions which may be encountered, it is recommended that both light and medium clothing and wraps be taken. Part of the trip will be very dusty, and old-fashioned "linen dusters" will be highly serviceable.

The itinerary given in the following paragraph will be seen to contain an important addition to the scheme already announced, namely, a trip to the Grand Canyon of the Colorado, which can be taken by those who can afford the extra time (about four days) involved, at a special reduced rate. If a sufficient number desire to take this trip, the special train will be divided at Flagstaff, Ariz., and one part will go on direct to Chicago, while another part awaits, at Flagstaff, the return of the Grand Canyon party. To those who have never made this trip, it can be said that the Grand Canyon presents, beyond comparison, the most impressive and memorable scenery on this continent. The trip from Flagstaff is a stage ride of about sixty-five miles, over a picturesque plateau, and the accommodations for travelers are comfortable, though not luxurious. The extra cost of this trip cannot be precisely stated at this time, but it is safe to say that it will not exceed $40, including the cost of holding part of the train at Flagstaff. Those who desire to include this extra excursion, the date of which is given below, are requested to notify Mr. Dwight immediately.

The following provisional itinerary is announced for the special train. Future changes will be promptly announced to those who have secured places in this train:

Sept. 15th.—Headquarters car, and probably one sleeper, leave New York at 1 P. M. by New York Central Railroad.

Sept. 16th.—Special train leaves Chicago at 5:30 P. M.

Sept. 17th.—Leave St. Paul, via Great Northern Railway, at 8 A. M.

Sept. 18th.—A stop of several hours will be made at Great Falls, Mont., to visit the works of the Boston & Montana Copper Co. and the Montana Smelting Co.

Sept. 19th.—The day will be spent at Butte, Mont., in visiting copper mines and smelting works.

Sept. 20th.—The concentrating and smelting works at Anaconda will be visited, and the train will leave at night for Spokane, Wash., by the Northern Pacific Railroad.

Sept. 21st.—Spokane will be reached early in the afternoon, and the train will leave for Portland, Or., about 6 P. M. by the Great Northern.

Sept. 22d.—Arriving in Portland in the evening, the train will continue to San Francisco by the Southern Pacific Railroad.

Sept. 24th.—The train will arrive in San Francisco.

Sept. 25th–28th, inclusive, will be occupied by the sessions of the meeting and by local entertainments.

Sept. 29th.—Special trains will leave in the evening for California mines, visiting Grass Valley, Nevada City, Oroville, Jamestown, Sonora, Dutch Flat, Redding, Sutter Creek, Jackson, New Almaden, etc.

Oct. 7th.—The party will reach Raymond, Cal., where the train will be left for the visit to the Yosemite valley.

Oct. 12th.—Los Angeles will be reached.

Oct. 13th (probably at a late hour), the party will reach Bisbee, Ariz.

Oct. 14th.—Visit to the Copper Queen mine.

Oct. 15th.—Arrive at Phœnix, Ariz.

Oct. 16th.—Arrive at Flagstaff, Ariz., the point of departure for a visit to the Grand Canyon of the Colorado. Those who take this trip will be delayed about four days, and a part of the train will wait for them. Those who continue their trip without stopping will reach Chicago, via the Santa Fe route, on Oct. 19th."

At the date of issuance of the above 178 members of the Institute and 36 ladies had secured places. It is thought that about 300 members of the association will make the trip.

FROM week to week the condition of things in the Transvaal has been referred to, but the past few days have seen the relations between the South African Republic and England strained almost to the point of rupture. Both sides evidently are in earnest and the Boers are hastily arming and placing soldiers at points of vantage. England has not been idle, and her troops are nearing the borders of the Transvaal, while active preparations are making to send a large army into the South African country from India, Egypt and England. It now looks as though war is inevitable. The Boers have refused to appoint members to a joint commission to inquire into the effect of the proposed changes in the law granting the franchise to Uitlanders; and while this in itself does not constitute an act of war, this refusal of President Kruger only tends to greater activity in the war department of Great Britain. The Boers profess to want peace, but desire England to recede from some of her demands. It is evident that the situation is being viewed by the majority of Uitlanders and England from a business and not a moral standpoint. The Boers impliedly threaten to destroy the mines and mining property at Johannesburg, in the hope that self-interest will impel the Uitlanders to advocate peace, though such vandalism would only make certain the very thing it was intended to prevent, insuring sharp reprisal.

ANOTHER accelerating motor—a sort of perpetual motion machine—has made its appearance in the market. It is known as the energizer momentum engine. The peculiarities of its construction are past explanation; but it may be said that it, together with all other mechanisms for which are claimed principles contrary to the forces of nature, is a "fake." No machine can transmit or produce power without a loss when compared with the generating force. A volume of water carried onto an overshot wheel is one of the most familiar applications of power, but the whole power represented in the weight of the water is not transmitted by the wheel. There is no such thing as accelerating or accumulating power in any device. Still the promoters of inventions of this class never fail in securing abundant capital for the promotion of their enterprises.

THE assertion is made in San Francisco that since the MINING AND SCIENTIFIC PRESS showed last Saturday the lack of power in the attempt of the last California Legislature to repeal the State mining law of 1897 Gov. Gage will call a special session of the Legislature to repeal that law—also to elect a U. S. Senator.

Concentrates.

GYPSUM is an excellent non-conductor of heat.

THE United States lead production for '98 was 220,000 short tons.

HEAVY stamps require heavier mortars and blocks than the lighter ones.

MONTANA mining men report an advance in the price of mining machinery.

ALASKA newspapers demand a Government mine inspector for that Territory.

A "GASH VEIN" is a mineralized fissure extending vertically a short distance, and comparatively shallow.

SHOES and dies must be of the same size, for if not the larger will cup and cause loss of crushing capacity.

THE object of substituting a steel for an iron rope should be to gain an increased wear from the rope rather than to reduce the size.

ALL pure gold is not of the same color. Australian gold has a reddish tinge, and some of the gold of the Urals is still more inclined to red.

WITH increasing altitude the boiling point of water decreases, until at sufficiently high altitude the hand could be immersed in boiling water without injury.

ORDINARILY gold amalgam will retort about one-third its weight if tightly squeezed. This varies considerably with the coarseness or fineness of the gold.

THE quantity of water used in a stamp battery varies with the character of the ore. It is advisable to employ as little water as will accomplish the work.

A PIECE of gold which weighed 640 pounds was found at Hill End, New South Wales, some years ago. It was claimed to be the largest single mass ever discovered.

AN explosive compound can be made by immersing the ter-chloride of gold in caustic ammonia. It is a dangerous substance and explodes when rubbed or struck.

IT is said by the owners that the Bonanza mine at Sonora, Cal., produced over $360,000 from a single pocket. Other pockets were found ranging from $50,000 downward.

STEEL flat wire ropes are composed of a number of strands alternately twisted to the right and left, laid alongside each other and sewed together with soft iron wires.

CARBONIC ACID GAS (carbon dioxide) has been drawn from the mines of New Almaden, in Santa Clara Co., Cal., compressed in steel cylinders and shipped for commercial uses.

UNDER the Federal laws of 1866, parallelism of end lines was not required; but under the law of 1872 parallelism of end lines was made essential to the exercise of the extra-lateral right.

WHERE a high head of water is not cheaply available, and a low head with large volume is easily obtainable, the latter should be adopted, using a turbine instead of an impact wheel.

AN administrator of a deceased entryman is without authority, under the homestead law, to relinquish the entry of the decedent, whether authorized to do so by the local courts or not.

GREEN GOLD made by jewelers is composed of twenty-five parts silver and seventy-five parts gold. Various shades of green are produced by varying the percentage of silver in the alloy.

RENEWING his subscription, a Moscow, Idaho, miner says: "Yours is the best paper for the mining man. I get enough out of any one number to pay for the whole year's subscription."

THE *Reveille* says that of the 2000 union miners in the Cœur d'Alenes all have left, except about 100. They have gone to Alaska, British Columbia and some to Butte, Mont., and the country south.

TO A CAPACITY of 100,000 gallons wooden tanks are believed to be superior to steel. With due care as to corrosion, steel is a good material to use for tanks of larger dimension than that specified.

THE U. S. Circuit Court in San Francisco has remanded back the anti-debris suit to the Yuba, Cal., Superior Court. The California State Miners' Association has engaged counsel for the defense.

EIGHT HUNDRED DOLLARS in United States gold coin weighs 43 ounces Troy. Nine-tenths of this is pure gold, one-tenth alloy. Hence, $800 divided by 38.7 gives $20.6718, the coin value of one ounce of pure gold.

STEEL ROPES should be of the best obtainable quality, as those made from low grades of steel are not as serviceable as good iron ropes. The constant bending and vibration soon causes poor steel ropes to become brittle and unsafe.

FOR guy ropes, stays, etc., galvanized ropes are superior, but galvanized ropes should not be employed for hoisting in mines, as the coating of zinc soon cracks off and, the corrosion of the iron following quickly, they become dangerous.

FOR safety in providing a rope for hoisting, allow one-seventh to one-fifth of its ultimate strength, in order to get good wear from it. In running ropes wear increases with speed, and for this reason it is better to increase the load than the speed.

THE term extralateral is used to denote the right to pursue a vein on its downward course outside of and beyond vertical planes drawn through the side lines of a lode location, into and underneath the surface of adjoining or contiguous land.

ALTHOUGH the law does not distinctly state that annual labor to the amount of $100 must be expended upon placer claims, the Land Department and the courts have held that the law of the lode claim applied also to placers and that annual assessment must be performed.

THE structural geology of the Calico, San Bernardino Co., Cal., region is not unlike that of Cripple Creek, Colo., substituting rhyolite breccia for the andesite breccia of Cripple Creek and liparite dykes and flows for the phonolite. There are also later intrusions of glassy rocks—vitrophyre and pearlite—in the Calico region; but these latter, so far as known, are not associated with any ore deposits.

AT Manti, Utah, a deposit of saltpeter, potassium, soda and magnesia, said to be the second deposit of its kind thus far discovered, the only other being in Germany, has been found. The owners expect to work the claims.

OCCURRENCE of cracks during rolling of brass is deemed due to impurities in the copper therein. Antimony in electrolytic copper used in the brass alloy will especially occasion such cracking, even when so small a percentage of antimony as 0.02 is present.

IT is not possible to temper steel in soapy water, for that is a non-hardener, because it does not rapidly abstract or conduct heat from the object to be hardened, and produces a heavy scale which sticks tightly to the surface, the scale being oxide of iron; this formation is the main preventive.

IN electrolytic extraction of zinc the ore is crushed, roasted, leached, the zinc being dissolved out. An electric current is passed through the solution, depositing the zinc at the cathode. In the Diffenbach process zinc chlorine produces the zinc by electrolysis; in the Siemens-Halske system zinc sulphate is used.

IT has been asserted that the appearance of native mercury in a quicksilver mine is an indication of an approach to the end of the deposit; but the facts do not seem to justify this conclusion, for the reason that cinnabar mines in California, in which native mercury was found years ago, are still in successful operation.

WITH metallic copper worth 18 cents per pound a unit (twenty pounds) is worth $3.60. The cost of treatment of copper ore varies with the character of the ore and the method of reduction. Some of the largest copper mines produce metal at a nominal cost of about 5 cents per pound. In most mines it is more.

SPECULAR IRON is a foliated, micaceous variety of hematite. Owing to its high metallic luster it is often mistaken for galena. An intimate mixture of galena and zinc blende is sometimes mistaken for tellurium ore. If zinc blende be treated with sulphuric acid the smell of escaping sulphuretted hydrogen is pronounced.

IF the end of a closed tube containing air is immersed in liquid hydrogen, the contents of the tube will be quickly condensed to solid air, and if the portion of the tube from which the air has been removed is sealed with a blow pipe, a vacuum will be obtained so high that it will scarcely allow the passage of an electrical discharge.

WHEN zinc spelter was selling at 7 cents per pound several years ago, the highest price obtainable for zinc ore was about $12 per ton. Now, with spelter at 5¾ cents per pound, zinc sulphide is selling readily at $45 per ton, and it is believed the business will become more profitable by the introduction of modern mining machinery and methods.

THE number of drops of a Gilpin county, Colo., mill ranges from twenty-eight to thirty per minute and the height of drop from 12 to 16 inches. In quick drop mills of the California type the drops average ninety-six, but in some run as high as 110 per minute. The latter is the extreme, and cannot be materially increased without the tappets striking the cams.

WHEN a slip joint is to be placed in connection with the discharge column of a pump in a mine shaft, place the sliding end uppermost—that is, the smaller pipe within the casing—otherwise any grit taken up by the pump and forced upward will settle around the inner pipe, filling the space between it and the casing and making it impossible to shift the pipe either way.

IN the issue of Oct. 15th, '98, is the illustrated article asked for, concerning boring for oil on the Santa Barbara, Cal., beach and pumping petroleum from under the sea. The drillers of these oil wells have no title except possession, but can thus hold their claims against all comers except the State. Title to these lands rests in the State, and the State can compel them to vacate—but is not likely to.

SOUTHERN CALIFORNIA'S present oil output is 5480 barrels per day. There is a present "boom" in oil in California, and new discoveries lead to the belief that in that direction lies largely the successful solution of the fuel problem. So far seventeen scientific articles have appeared herein, giving complete information, written with full practical knowledge of the subject, and the series will be continued.

PERFORATED tin screens for quartz mills are preferred by some for the reason that they are cheaper than Russia iron screens, though tin plate is only sheet iron tinned. These screens are burned before use, to oxidize the tin. If this precaution be not taken the tin amalgamates with the mercury and clogs the holes. The use of perforated tin for such purpose is not recommended, as iron is, on the whole, more economical.

IN a new process for preserving and fireproofing timber the wood is first impregnated with lime milk, and then with a solution of ammonia and boric acid. The milk is forced by a pump into the pores of the wood, which is in a partial vacuum chamber. Dry air is then forced through the chamber, and when the wood is dry the ammonia solution is applied. P. & B. paint continues to be used for such purposes with satisfactory results.

NATIVE GOLD, though yellow by reflected light, is green by transmitted light. When silver is employed as an alloy the color of gold by transmitted light is light green. When alloyed with copper the color is emerald green or even blue by transmitted light. When in a state of fusion, gold often exhibits a bluish green tint, and at a higher temperature it gives off purple vapors. It is one of the most perfect conductors of heat and electricity.

WHERE a tunnel is located for the development of a mine or group of mines, when the tunnel is outside of the limits of the mines to be benefited, assessment work may be done in the tunnel, and the holder of the claims is not required to perform work on the surface or elsewhere on the claims. The amount of work performed in the tunnel must equal $100 annually for each of the claims in the group for the development of which the tunnel is run.

WHEN an ore shoot pinches in depth and the vein walls continue and remain well defined, there is no positive assurance that another shoot will be found at greater depth, though this has been found to occur so frequently that there is a reasonable inducement to explore deeper in hope of finding such deposit. Not infrequently ore shoots are found to offset a few feet, the ends overlapping, but separated by vein material a few inches or several feet in thickness.

THE use of hydraulic separators in gold mills is recommended for sizing pulp before sending onto concentrating machines. A machine which will save a relatively large particle of sulphide with a given number of vibrations, quantity of water and grade, will not save a very fine particle of the same mineral. For this reason pulp which has been sized and delivered to different machines set to treat each particular class of material results in better work and a closer saving.

COPPER in ore is generally believed to be detrimental to the successful operation of the cyanide process. Such, however, does not always appear to be the case. Oxidized ores cause more trouble than sulphide ores. Some copper sulphides fresh from the mine which have not suffered oxidation give less trouble than those which are partly oxidized. Some mill managers keep iron and other sulphides which are to be treated by cyanide process under water to prevent oxidation.

WIRE ROPE must not be coiled or uncoiled like hemp rope. It should be mounted on a reel and rolled on or off as required. When receiving a new rope from the manufacturer that is not on a reel, but coiled up, the best way to put it in place is to take the coil to a distance from the shaft equal to its length and, releasing one end, roll it along the ground like a wheel, until it is entirely unrolled, when the end nearest the shaft may be passed over the sheaves and onto the hoisting reel and wound up.

THE law requires that labor shall be performed or improvements made upon each claim until a patent has been issued therefor. When application for patent has been applied for, proofs made and money paid, the equitable title of the purchaser is complete and the patent when issued is evidence of the regularity of the previous acts. In short, an entry made is in all respects equivalent to a patent issued, in so far as third parties are concerned.

THE main object in the regulation and adjustment of a quartz mill is to crush as much rock as possible with the available power within a stated time and to keep the loss of gold as low as possible. When a certain stage is reached it is usually found to cost more to save the gold remaining in the tailings than the value of the gold itself. After the highest saving with the greatest capacity has been attained, a few simple automatic devices may be introduced to save a little closer, in the way of mercury traps, etc. These require little attention and are cleaned up when occasion requires.

THE formation in which a vein occurs has little to do with the value of its ores. The condition of the wall rocks, however, is sometimes an indication which may guide the miner in his search for ore. When the vein occurs in a rock which in its normal condition is massive, like granite, diorite or diabase, and the wall rocks are found altered to a schistose or slaty condition—softened and mineralized—ore may be looked for, though it may not always prove to be pay ore. No hard and fast rules have been found applicable to all cases. A dyke may have a beneficial effect on a vein, but rich veins exist which have no dykes near them.

REGARDING steam engines exhaust the successful application of the cooling tower to the condenser renders it possible for steam users to run their engines condensing with economy of water use. In textile mills it is a common practice to operate engines with several pounds back pressure on the exhaust steam for the purpose of utilizing the exhaust for heating purposes. With the compound condensing engine, steam of about the right pressure and temperature can be taken from the receiver, thus furnishing it under the most economical conditions, and, at the same time, allowing the use of condensing engines.

GOLD is deposited in segregated bunches of greater or less size, as irregular masses, crystals, dentritic infiltrations, in foliated, fernlike and other forms in crevices in the rocks, and are called pockets. The genesis of these accumulations of gold is not understood, though it has been observed that they frequently occur in veins at the intersection with cracks which have a strike and dip differing from that of the vein. Sometimes they are found where a change of formation takes place. While there is a great variety in the conditions under which pockets occur, they are usually found in any particular mine surrounded by similar conditions.

THE California mining law of May 26th, '97, provides as follows: The discoverer of any vein or lode shall immediately, upon making a discovery, erect at the point of discovery a substantial monument or mound of rocks, and post thereon a preliminary notice, which shall contain the name of the locator or locators; the date of discovery; the number of linear feet claimed in length along the course of the vein each way from the point of discovery; the width claimed on each side of the center of the vein; general course of the vein or lode, as near as may be; that such notice is a first or preliminary notice. The notice shall be recorded in the office of the county recorder of the county in which the same is posted within twenty days after the posting thereof. Upon the erection of said monument and posting such notice the locator shall within sixty days of the discovery perform $50 worth of labor in developing his discovery, and distinctly mark his location on the ground, so that its boundaries can be readily traced, and must file in the office of the county recorder of the county in which the claim is situated, a certificate of location, which certificate shall state: The name of the lode or claim; name of locator or locators; date of discovery and posting of preliminary notice, which shall be considered as date of location; a description of the claim defining boundaries, and such additional description by reference to natural objects as will identify the claim. Also a statement that such certificate is the final or completed notice of location, and that he has performed aforesaid $50 worth of labor in development work thereon within the aforesaid period of sixty days. The certificate shall be dated and signed by or on behalf of the locators and verified by them or some one in their behalf, and when filed for record shall be deemed prima facie evidence of the facts therein recited. A copy of such certificate of location, certified by the county recorder, shall be admitted in evidence in all actions or proceedings with the same effect as the orignal.

Mining Activity in Eastern Oregon.

From a Staff Correspondent.

One of the most active sections of the Northwest the present season is that tributary to Sumpter, Oregon. Such mines as the Red Boy, Columbia, Bonanza and North Pole are working with greater results than ever, and such new properties as the Golconda, Cougar, Magnolia, Little Giant, Vananda and May Queen are being rapidly developed and equipped on a scale that involves the expenditure of half a million dollars the present year. The Sumpter Valley Railroad, whose line extends from Baker City to Sumpter, thirty-one miles in length, is doing a heavy business in freight and passenger traffic; and the town of Sumpter, built in a narrow valley among pine trees, is having a good growth. It has a population of about 2000, and, being the outfitting point for the mines, villages, sawmills and ranches from Bourne (on Cracker creek) to Canyon City (on the John Day river), it is a busy place.

The good record and success of a number of mines in this vicinity have established confidence and imbued the district with enthusiasm, the result of which is seen in the purchase of a number of prospects by Seattle, Spokane, Chicago and Montreal men; and the activity displayed by the newcomers in pushing development work and building mills is evidence of substantial backing.

In the Columbia, North Pole, Red Boy and Bonanza, which are extensively developed, the ledges of ore are known to be of good width, well-defined, extensive and the ore of good grade. The development so far pursued on the newer properties, such as the Golconda, Cougar, May Queen and Magnolia, discloses ore bodies apparently as extensive and as rich as those in the well-developed mines.

Those properties now attracting special interest may be grouped in four sub-districts: First, at Bourne, are the North Pole, Eureka & Excelsior, Columbia and Golconda, which are located on the same mineral zone; second, near Granite, the Cougar and Magnolia mark the location of another base of operations; third, the Red Boy, May Queen, Vananda and others comprise an important group; fourth, the Bonanza and Richmond have opened a number of great ledges of ore which makes Bonanza or Geiser a district within themselves. Tributary to and included in each of those sub-districts are other properties of merit which are being developed. The ores from all this section are similar, being oxidized quartz, mineralized porphyry and talc, carrying free gold, running into sulphides at greater depth. The veins are usually between slate walls. There are five or six mills operating in the vicinity, in all of which the principal values are saved by amalgamation, concentration of tailings being an important item. The North Pole mill, however, has a combination process, which, under Mgr. Melser's directions, is doing good work. It includes amalgamation, concentration and cyanidation. The Red Boy mill of twenty stamps and eight concentrators is to be supplemented by a forty-ton cyanide plant for working tailings.

Above are given the general features of the district. A more particular notice of the several mines, however, may be of interest:

The Columbia, under the management of Frank S. Baillie, is putting in a new hoist, two 100 H. P. boilers and a six-drill compressor. The hoist will be capable of working to 1000 feet depth. A shaft is being sunk to a depth of 500 feet below the main tunnel. About 8000 feet of work is laid out for the rest of the year. The ten-stamp mill saves 40% of the values on the plates, and about fifty tons of concentrates are shipped per month. The building of a new and larger mill is contemplated.

The Golconda is developed by two main tunnels, one of which goes in 750 feet in the foot wall and another 150 feet in hanging wall, a crosscut connecting the two. Half way between them a shaft sinks 250 feet from the tunnel level, from which are drifts in opposite directions to the vein walls. In the aggregate, there is 1800 feet of work done. On or near the surface the ores contain considerable arsenic and antimony, but at greater depth these elements are said largely to disappear, leaving the ores chiefly iron sulphide, adapted to concentration. The principal values are gold. It is 100 feet in places from wall to wall, there being within this rich streaks about 3 feet wide. On this property is the electro-chemical process mill—the chief agent in which is chlorine—patented and devised by Greenawalt & Robinson of Denver, Colo. In structure and equipment the mill is extensive and complete and is said to have cost $100,000. As yet it has not commenced to run regularly and it is too early to more than casually speak of it. Its operation and the results therefrom will be watched with much interest. Mr. J. G. English, owner of the property, is not sparing money to give the process a fair trial. W. H. Jackson is mine superintendent.

The North Pole mine and mill are operating steadily, being owned by the Eastern Oregon M. Co. It is considered one of the substantial and well-managed properties of this section.

The E. & E. has been closed down for several months, by reason of various complications, and it is claimed a sale is pending.

The Cougar group is owned by J. W. Larkin and D. R. Evans. It is opened by a drift on the ledge 600 feet, the ledge being reached by a crosscut tunnel. The vein is said to run from 3 to 20 feet between walls and has been opened by surface cuts for a distance of 1500 feet. Further development is being conducted through a shaft on the ore body. The ores are claimed to run $75 per ton. A 250-ton cyanide plant is being built on the property, it being considered that the ores are adapted to this process. This will be one of the largest mills in Oregon.

The Magnolia is being developed by W. L. Vinson and associates. Three tunnels—650, 495 and 300 feet, respectively—all following the strike of the ledge, develop a good showing of ore from 2 to 5 feet wide. The values here are good.

RED BOY MILL, NEAR GRANITE, OREGON.

The May Queen has made substantial progress within the past year, and I am informed by Mgr. Geo. J. Barrett that a 10-stamp mill is to be erected this season. The property is well developed by a series of tunnels, connected by upraises. The work aggregates 1500 feet. The ores are oxidized and free-milling, running from $8 to $10 per ton. This ore is similar to that of the Red Boy, which is doubtless on the same zone.

The Red Boy has an 1100-foot crosscut tunnel which cuts three parallel veins. The first vein, 600 feet from the tunnel entrance, is opened by drifts 400 feet each way from the tunnel, with large stopes. The second vein—800 feet from mouth of tunnel—has practically the same amount of drifting as the first. The third vein will soon be reached by the advancing work in the tunnel. The veins vary in width from 8 to 20 feet. As in various other mines of this section, the walls are porphyry and slate. The Red Boy mill is run by water power, there being four wheels under pressure of 120 feet head, conducted through a two-mile flume. Mr. Taber states that 75% to 85% of the values are saved by amalgamation. About sixty tons of ore per day are being milled.

The Vananda, two miles from the Red Boy, belonging to Blewett & Co., is being developed with a force of fifteen men. Three crosscut tunnels are being driven. Buildings and other improvements are being put up. The intention is to erect a mill.

The Little Giant development is being pushed by Vinson & Thompson. They have a tunnel 350 feet long to the ore body and two drifts on the ledge. Plans have been made for a stamp mill.

The Virginia, at Robinsonville, belongs to J. H. Mitchell and is said to be under bond to Blewett & Son. This property has a 165-foot shaft, with 300 feet of drifting from the shaft on the vein. Further sinking is to be done. The June Bug, belonging to F. Hopp, is also under bond. The Don Juan, belonging to Donnelly & Graham of Denver, Colo., is equipped with a 10-stamp mill, which is ready to operate.

The Bonanza was sold by Geiser Bros. last April to a syndicate of Philadelphia oil operators. Messrs. Geiser took the property eight years ago with an indebtedness of $8000 against it, and up to the date of the sale last April they had taken $1,100,000 from its veins. The figures agreed on in the sale are not given the public. The mine is developed by 10,000 feet of workings, there being one tunnel 2000 feet long on the vein and another of 2000 feet which crosscuts the veins. A third upper tunnel is 1500 feet long. A shaft is sinking from a point on the main tunnel 1100 feet from entrance. These workings disclose three or four parallel veins, the first being 3 to 4 feet wide, the second 10 to 50 feet and the third about 15 feet in width. The vein wall is slate, the ledges running eastward and westward. The work all begins at the south wall, and it is asserted that the north wall has never been found. The ores are free-milling quartz, with sulphides of iron, interspersed with streaks of tellurium. The last-named mineral appears to be peculiar to this particular property, as it has not been found in other mines of the district. Last year 8000 tons of ore were milled, the result being an average of $14.54 per ton, outside of rich streaks of tellurium, which ran from $400 to $1100 per ton. The mill is being enlarged to forty stamps and a ten-drill air compressor has been installed.

Adjoining the Bonanza is the Richmond group, belonging to Montreal parties and managed by E. D. LeClaire. They are undoubtedly on the same zone as the Bonanza.

Development is in progress through a system of tunnels aggregating 1500 feet, all being crosscuts. These tunnels are so located as to open up the ore body the full extent of their holdings. The ores run $6 to $15 per ton. A 10-stamp mill is to be built.

BONANZA MILL AND COMPANY'S BUILDINGS, NEAR SUMPTER, OREGON.

On the north fork of the John Day river the Grant placers are being worked under lease by Isaac Klopp. A canal, fourteen miles, and a flume, 1600 feet long, furnish water under 200 feet pressure. Mr. Klopp is operating with two giants and says he is obtaining good results.

The Bellevue, which belongs to Salt Lake parties, resumed operations last spring and is expected to increase the force. The work is in charge of Peter Roden, with Frank L. Robb as mill man.

It is asserted that Idaho and Montana parties will build a gold dredger to work on the Drain flats, near the north fork.

WASCOTT.

Sumpter, Or., July 31st, '99.

West Kootenay Ore Bodies.*

By R. W. BROCK, Ottawa, Canada.

Within the limits of this paper it is of course impossible to do more than take a brief and general survey of a field as extensive and varied as West Kootenay. It is proposed merely to review briefly some of the observed facts relating to its geology so far as it is connected with the ore deposits, and to the ore deposits themselves, and to indicate to some extent their practical bearing. Some of these observations may have been already recorded, others have been suggested as being probable and now stand confirmed in the light of further study. If any apology is needed for such a restatement let it be that such observations have a direct economic importance, for anything that contributes to a more exact and definite conception of the nature and mode of formation of a group of ore deposits has a commercial value, since it makes possible more intelligent exploitations of the particular members of the group, and more accurate forecasts, beyond present workings, of their probable form and extent. In discussing the ore deposits, while it is possible to separate them into a number of different classes, it is here proposed to touch upon merely some general features. The progress, prosperity and possibilities of the district are now so well known, and can be so eloquently supported by statistics, that it is quite unnecessary to go into such matters.

Geologically the district is a complex consisting of several series of crystalline schists and stratified rocks, dyked, metamorphosed by, and caught up in multifarious eruptives, which in turn treat each other in like manner. The crystalline and stratified rocks, while limited in distribution, include a considerable variety.

There is a series of gray gneisses, mica schists, quartzites, crystalline limestones and dolomites with old intercalated crushed igneous rocks. These rocks have been referred to as of probable Archæan age. They occur typically developed on Kootenay lake north of Crawford bay, and the West Arm. They are also found on the north end of Slocan lake, on Slocan river, at the head of Snow creek, and on Upper Arrow lake. Numerous small inclusions of gneiss in the eruptives in various portions of the district may probably be also referred to the Archæan.

A series of slates occurs, more or less altered to mica, staurolite and andalusite schists, with bands of greenish schists, quartzites and dolomites. This series has been classed with the Nisconlith series of the Cambrian. It is most largely developed in the southern portion of the district where a band several miles in width, interrupted once or twice by granite intrusions, extends from a point just south of the West Arm of Kootenay lake, a little east of Nelson to the international boundary. Along the boundary it has considerable width, extending from four miles east of the Pend d'Oreille crossing to within a few miles of its mouth at Waneta. It is also found in a narrow band north of Kaslo, parallel to Kootenay lake a short distance inland. Rocks which may also be referred to this series occur near Deer Park, on Cariboo creek near Burton City, and on Upper Arrow lake.

This series is overlain by a great thickness of rocks that have been classed with the Selkirk series. They are found east of the Salmon river on the divide between the Salmon river and Kootenay lake at the head of Wild Horse, Sheep and Lost creeks and down Summit creek for half its length. They are also found east of Kootenay lake from about Lockhart creek to near Gray's creek. They also occur in a band west of Upper Kootenay lake, succeeding in a westerly direction the Archæan and Nisconlith rocks. This band, north of Kaslo, gradually tapers as it continues southward till it runs out near the West Arm.

On Summit creek they are apparently overlain by a great volume of quartz and mica schists which extend eastward to Kootenay lake. These are classed as Upper Selkirk.

Another important group of stratified rocks is that known as the Slocan series. They consist of a group of dark and banded rocks composed of tuffs and ash rocks with some impure slates and limestones. They occur all around the north end of Slocan lake, southward, cut by one or two granite bosses, as far as Four-Mile creek, and eastward to the forks of Kaslo creek. From here a band extends south to the West Arm between the band of Selkirk rocks and a great granite mass. Similar rocks also occur on Cariboo creek.

Varied as are the schists and stratified rocks, the eruptives show still greater complexity. Among the oldest and most important, economically, is the Columbia group of volcanics. This group includes porphyrites of various kinds, monzonites, diabases, gabbros, breccias, tuffs, agglomerates and dark, fine-grained slatey ash rocks. The monzonites are interesting rocks, both on account of their petrographical peculiarities and also as being the country rock in the War Eagle, Le Roy and other Rossland mines. It is a peculiar type of rock referred to the syenite family. It exhibits wonderful differentiation ranging according to relative proportions of feldspar and colored constituents through syenitic, dioritic and gabbroitic types. Along the border of a mass it may present even a more basic facies.

The Columbia volcanics cover a considerable area. They are largely developed in the Rossland district and also east of the Columbia, where they extend eastward to the Salmon river and northward to the west arm of Kootenay lake and Kootenay river. Around Nelson and along the Columbia river they are cut off by granite, a large mass of which extends as a peninsula from the Columbia eastward into the volcanics. Porphyrites and associated rocks, which are probably to be referred to this group, occur on Arrow lake in the neighborhood of Deer Park, and up Cariboo and Snow creeks behind Burton City.

Younger than, and cutting all the rocks so far mentioned, is the gray granite, the commonest rock of the district. It is a biotite-hornblende granite, usually, but not always, gray in color. It varies considerably in texture and composition, being in places syenitic or dioritic, but apparently having a prevailing granitic habit. The feldspars are often large and porphyritic, in which case it is very striking and easily recognizable rock. When crushed, as it sometimes is, this porphyritic facies makes a beautiful augen gneiss. In occurs in large and small areas throughout the entire district, and is intruded through all the older rocks. A typical development of this rock may be seen at Nelson. Another granite, younger than the gray, is the older red granite, a very feldspathic rock found on Lower Arrow lake near Deer Park, and elsewhere along the Columbia valley.

Under the head of younger eruptives may be grouped a series of rocks which show a wide range of structure and composition, ranging from plutonic to volcanic types, from granitic to at least dioritic. They are sometimes developed in quantity, as the younger red granite along Lower Arrow lake and also near Trail creek, and northwest of Rossland. As dykes they occur in almost every part of the district, cutting all the older rocks.

The most important of these dykes are the white porphyries. These are usually white, compact dykes varying in size from broad masses to little stringers which cut sharply through the country rock. So far as is yet known, in structure and composition they appear to range from rhyolites to diorite porphyries, including felsites, granophyres, granite porphyries, and syenite porphyries. The acid, however, appear to be the prevailing types, at least in the northern part of the district and along the Salmon. Though varying in character these dykes may usually be recognized by their light color and their sharply defined contacts with the country rock. Near Rossland and in some other portions of the district darker types are, however, to be met with. This system of dykes seems to have immediately preceded the formation of the ore deposits.

Younger than this system of dykes and the ore bodies, and consequently cutting these, are the "black dykes," a group of lamprophyric and basaltic dykes.

The above constitute the main groups of rocks of the district so far as connected with the ore bodies. They present many facies, which have not been here noted. Other rocks occur, as comparatively fresh andesites, diabases and such volcanics, but these have not been observed to be connected in any way with the ore deposits.

The economic minerals which may be found in the ores are also various, as the following list shows: Native gold, silver, copper and arsenic; stibnite, bismuthinite, tetradymite, molybdenite, argentite, galena, altaite, hessite, chalcocite, stromeyerite, sphalerite, cinnabar, greenockite, pyrrhotite, bornite, chalcopyrite, pyrite, gersdorffite, marcasite, arsenopyrite, danaite, jamesonite, pyrargyrite, proustite, tetrahedrite, tennantite. The gangue is principally country rock, quartz, siderite, calcite, sphalerite. Oxidation products of the metallic minerals, such as the oxides, carbonates, sulphates, are found in the weathered zones.

The above list could probably be enlarged, but it will serve to show the variety and general character of the economic minerals.

The character of the ores varies more or less with the district, thus in the Rossland ores the auriferous iron and copper sulphides predominate, in the Slocan the lead and silver minerals with argentiferous tetrahedrite are characteristic, while the Nelson district mineralogically as geologically lies between the two. But while in the different portions of the district there is considerable variation in the relative proportions and mineralogical combinations of the principal elements, the elements themselves remain practically the same throughout. But why in one place the ores should be mostly silver-lead minerals, and in another mostly auriferous iron and copper ones, or why in one place there should be large bodies of metallic sulphides and little gangue, and in another the value should be in a small quantity of sulphides and much gangue, or why the silver and gold tenors should vary so, are points which cannot yet be very well explained.

It may be remarked, however, that the production of the quartz vein appears to have been about the last stage in mineralization; also that in places it appears that the country rocks exerted some chemical influence, causing the deposition of iron and copper sulphides in the massive rocks and the silver-lead in the fragmental, but this has not always been the case.

As to the age of these deposits nothing definite can be asserted, except that while the evidence tends to show that they are comparatively recent, they are certainly pre-Pliocene.

On account of their comparatively recent formation and the fact that the factors which determined the deposition were physical rather than chemical, they may be looked for in all the rocks except the latest dykes (and probably the younger eruptives) wherever the physical conditions are favorable.

As to manner of formation, the evidence afforded is conclusive that they were formed by mineralizing solutions, which followed lines of fractures, dissolving away the country rock and replacing it with mineral matter. In a large ore body, or where the country rock is a homogeneous one, such as some of the Slocan rocks, this history cannot be so clearly read as when the deposit is small and the country rock is a heterogeneous one, such as granite. Here it is sometimes possible to trace the alteration from the unaltered granite to the solid sulphides; first the more easily decomposable constituents show signs of alteration, then one constituent is removed and replaced, then another, until of the original rock only a skeleton of quartz remains, and finally this is almost completely or wholly replaced. But even if the process had not been exposed as in the example above, the evidence would still be complete. For in many of the large deposits cores of the unaltered country rock still remain; the country rock near the deposit has often been silicified, producing "capel" like bands. This silicification has proceeded in places until it almost amounts to complete replacement. Calcification in places has also been extensive. The country rock has often been more or less mineralized, and if it contained feldspars, bisilicates, and such alterable minerals, these often have been attacked in such a way as to indicate the action of hot mineralizers. In one case on Pine Ridge in the granite adjoining a small deposit, the feldspars have been altered, pyrite probably represents what once were bisilicates, and a violet-colored secondary fluorspar has been disseminated through the rock. A violet-colored quartz present is probably of the same origin as the fluorite.

Very little work has been done on the chemistry of these deposits and consequently few chemical data are available, but what there are afford additional evidence. In a paper by Gwillim and Johnson on "Some Ores and Rocks of Southern Slocan," in the Canadian Record of Science, the following analyses are published:

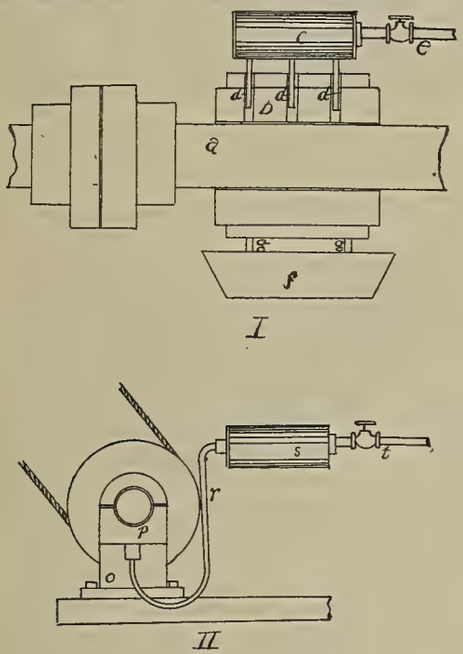
	(*a*)	(*b*)
SiO_2	60.09	70.70
Al_2O_3	17.20	18.25
Fe_2O_3	6.73	3.18
MgO	0.47	2.12
CuO	8.24	3.36
Na_2O	2.45	not estimated
K_2O	6.23	" "
H_2O	not estimated	" "
	101.41	98.61

(*a*) is an analysis of the country rock, a facies of the gray granite.

(*b*) is an analysis of a horse of this rock in an ore deposit.

As the localities of the two specimens are not given, an exact comparison between the analyses cannot be fairly made, but still (*a*) may be taken as expressing in a general way the chemical nature of the country rock to which (*b*) belongs. The water in an altered rock like (*b*) would probably be sufficient, if estimated, to raise the analysis to 100, so that the alkalies are here practically absent. In the unaltered gray granite their percentage is high. So that in the horse the large percentage of alkalies has been practically removed, together with the greater part of the lime and a large part of the iron, while there has been a corresponding raise in the percentage of magnesia, alumina and silica. This is the alteration to be expected in a rock subjected to thermal waters containing such reagents as carbonic acid and sulphuretted hydrogen.

(To be Continued.)



* Condensed from Transactions of Canadian Mining Institute.

A METHOD of removing the incrustation of boilers is announced by a French engineer, M. Savreaux. After extinguishing the fires, the boiler water is blown off very gradually, at the same time admitting an equal volume of cold water, so that the water gauge shows no change of level. As soon as the water has in this manner been sufficiently cooled down it is suddenly blown off. This latter operation is said to remove the major part of any incrustation which may be present, what remains being very easily detached by scraping. The cleaning of the boiler must, however, be taken in hand immediately upon completion of the blowing-off operation, as otherwise the furstone will harden and adhere again to the boiler plates.—The Engineer.

Notes on Power and Transmission.

Written for the MINING AND SCIENTIFIC PRESS by GEO. D. RICE, Medford, Mass.

Since the advent of so many methods for the filtering of oils so that the same may be used over and over again, power users usually plan exposed cable bearings in such a way that an abundance of oil will flow to the part and the surplus is caught, filtered and used again. I have put in oiling outfits like that

LUBRICATING DEVICES.

in Fig. 1 for exposed bearings of cable drives. A pump supplies oil through *E* to the cylinder *C* and the oil flows to the bearings through three leaders or tubes *D D D*. These tubes sink into oil channels in the box *B* and feed the oil liberally to the shaft *A*. The tank *F* is connected below by bolts *G G*, and when full of oil which runs from the bearings it is emptied into the filtering device and the oil used again. In some places the strain on both shaft bearings and belts is relieved over night and Sundays by means of automatic devices. How frequently we hear that belts need rest, and that there should be some way provided for running them off to recuperate a trifle over night, and, in fact, there are many concerns fitted up with binders for this purpose, to be slacked when the speed shuts down for the night, and tightened to the best running condition when the work starts up again. On the other hand, belts may be seen, when new, subjected to a steady strain for a long while, in the hope that they will never need taking up or give trouble by growing slack. Some very good and simple methods consist in using half-moon sleeves in the pulley hubs, which allows the belt on two pulleys to be slackened by merely shifting the moon piece on the loose pulley. The shifting is done with a clutch and bar. The material from which the belts are made has a little of that tendency to be drawn out of shape by the constant pull and the rolling-out action it receives from the tread of the wheels, and should have a chance to regain itself when idle, as long as that is one of the features of leather belting. Care should be taken to keep the laps of the belts in good condition. In the making of the belts, after the pieces of leather are thoroughly stretched they are worked smooth on the grain side, and both by hand and by machine labor are set down as solid and compact as possible. Then they are put into a drying room and thoroughly dried. Afterward one edge of the piece is straightened, and they are then cut into whatever width of belt they are best suited for. The pieces of each width are matched accurately as to thickness and then the laps (joints) are cut by a machine. The edges of the laps are feathered and the joints are cemented (glued) together and pressed under a hydraulic press, which pressure is considered the best by all first-class belt makers. All main driving belts over 40 inches in width have to be made in sections, consisting of two or more pieces of leather cemented together. The average hide for belting does not contain more than 40 inches in width of solid leather suited for belting, very rarely over that. Therefore wide main belts are made in sections. Ordinarily the pieces are not lapped parallel, but simply butted. For example: A 60-inch double belt receives two 30-inch pieces for the first layer, laid side by side, and a 30-inch piece over the center of the two lower pieces to break the joint, and two 15-inch pieces on the top of each edge of the lower layer to complete the width; thus the belt is cemented together. There is some difference in throwing on new belts and lacing up old ones, for it takes some skill and a little good judgment to get the best working tension for a belt that is to be laced up for the first time, while in taking up slack belts all that is required is to cut out a row of holes and lace up again, which will certainly improve the driving qualities, for a time at least. A belt and clamp that works on the pulley block principle seems to be a good device in this respect, as the tension on the drawing-up cord can be easily determined with spring balances.

Oiling Under Water.—In Fig. 2 is a plan used with effect for lubricating a cable wheel under water. The oil is forced into the receiving tube *S* through pipe *T*, from whence it passes through pipe *R* to bearing *P*. The main bearing of the wheel is indicated at *O*. The oil, being taken in at the bottom of the bearings, works upward and lubricates the parts with effectiveness. Water undoubtedly acts to reduce friction, but where it is only present in small proportion it can have but little effect. Indeed, in such cases it seems to act to render the oil less efficient rather than to increase its efficiency, probably because the water prevents proper oiling. There can be no doubt that the absence of a lubricant increases friction, and unless there is some condition to call attention to the lack of lubrication it often passes as not needing lubrication. That a bearing does not groan and act as though badly in need of oil is by no means evidence that the friction would not be decreased if oil were used.

Oily Scale.—An oily scale matter sometimes forms in boilers and produces trouble. This scale is composed of fatty acids and unsaponified oils, derived from the oils used to lubricate the cylinder of the engine. These elements are communicated to the feed water where the exhaust steam from a non-condensing engine is used to heat the feed, or where the feed is drawn from a hot well of a condensing engine. The deposit is an effective non-conductor of heat, and is a most frequent cause of overheating and consequent collapse of the boiler. The substitution of a good mineral oil, with a boiling point well above the temperature of steam, instead of the animal and vegetable oils frequently used in cylinders, is the best safeguard against the production of that very injurious form of scale.

Repealed or Not Repealed?

TO THE EDITOR:—The question whether or not the Cal. State mining law of 1897 has been repealed is one which must be passed upon by the court of last resort before it will be authoritatively settled. In the meantime miners are left in a quandary as to the manner of making locations. If they proceed upon the theory that the attempted repeal of the State law is effective, and the Supreme Court holds it to be ineffective, their acts of location will be void. On the other hand, if they proceed under the State mining Act of 1897, upon the theory that it is not repealed, and the Supreme Court holds the repeal effectual, they may be in an equally bad predicament, for a preliminary notice posted and recorded as provided in the State mining Act is not necessarily a compliance with the Revised Statutes; and, in the case last supposed, a subsequent notice posted and recorded by another locator prior to the recording of the certificate of location by the first locator might give the better title. In fact, it would most certainly do so if the first locator proceeded strictly under the requirements of the State law and the second locator included in his notice "such a description of his claim by reference to some natural objects or permanent monuments as will identify the claim," for the State law only required this in the certificate of location, and not in the preliminary notice, while the Revised Statutes provide that no recorded notice shall be sufficient unless it contain such a description of the claim. All of the printed blanks of preliminary notices under the State law that I have ever seen are entirely insufficient in this particular, and would not stand in the face of a contest if the State law should prove to be repealed.

Every locator who desires to make himself perfectly safe, and to be assured of having a perfectly valid location in either contingency, should locate as provided by the State law of 1897 and do his $50 worth of work within sixty days, as therein required; but he should also be particular to insert in his preliminary notice, as well as in his certificate of location, a particular description of his claim by reference to some natural object or permanent monument, sufficient to identify the claim. If he uses a printed blank, he should write in such a description.

Personally, I believe the Supreme Court will uphold the sufficiency of the repealing act of 1899. The able opinion of Mr. Ricketts in your last issue leads to the opposite conclusion, but there is a point of view which that gentleman has evidently not considered. It is this: It is admitted by all authorities that, when the meaning of the language in the body of the Act is doubtful, the title, taken in connection with other parts of the statute, may be resorted to for the purpose of removing ambiguity. Now in this case there is a manifest ambiguity in the body of the Act because the Supreme Court has, and must take, judicial notice of the fact that there is not and never was such an Act as is referred to in the body of the statute under consideration. There is therefore an obvious error upon the face of the Act in question which may easily be corrected by a reference to the title. This is not judicial legislation, because the error and its proper correction are both patent upon the face of the statute.

The case of Wilson vs. Spaulding, 19 Fed., Rep. 304, is exactly in point. In that case a statute purported, in its body, to correct Schedule M of Sec. 25 of the Revised Statutes of the United States, while Sec. 25 had no Schedule M. A reference to the title, an Act to "correct an error in Sec. 2504 of the Revised Statutes," etc., was held permissible to explain and rectify an obvious error.

The pertinency of this decision of the case in point must be as apparent to the layman as it is to the lawyer, and there are numerous other decisions of similar import. W. F. ARAM.

San Francisco, August 16, '99.

Some Experiences of a Working Miner,

NUMBER XXIX.

Written for the MINING AND SCIENTIFIC PRESS.

A prospector found the V—— mine. He worked on it a short time, but, not being familiar with methods of handling the ore, sold it. A company was organized by the new owners, of which T—— was the head. A large amount of money was expended and machinery erected. For a time all went well; but the company made the same mistake that so many others had made before and many have made since—they went into debt—and their creditors finally took possession and the mine remained idle for a long time. Finally it was brought to the attention of C——, who, upon examination, concluded he could make the proposition pay if handled carefully. The property was miles from a railroad, in a treeless region. Wages, supplies and transportation were high. Still, these drawbacks did not deter C——. He understood just what was essential to success, and, making all the necessary allowances for the conditions, he put in a plant suited to the ore, employed competent superintendents for each department, purchased adjoining property and commenced operations on a liberal scale. Success followed, and the plant was enlarged from time to time. Fortune seemed to favor the bold venture, for, although the outlook was good from the start, the value of the ore improved, and new, greater and richer bodies were discovered. To-day the U—— V—— is one of the greatest mines in America; but it has always had, what every mine should have, careful, intelligent and experienced management.

* * *

There was unusual activity in tin mining when C—— located a claim near H—— City. He put a shaft down 15 feet, and had a fine showing of ore, too—a clean vein in the bottom of the shaft, with 4 feet of good ore. At this depth he quit sinking and put in time prospecting on other portions of the claim. One day a man came along who wanted to examine the prospect, of which so much had been said. C—— showed him the prospect holes; then they climbed down into the shaft and examined the vein. It looked all right, and the stranger offered $8000 for the prospect. C—— wanted $10,000, and finally got it. The stranger wanted immediate possession and to continue work. C—— said no—cash first. The stranger returned the following day with the cash in bank bills. The mine was transferred and then C—— invited the stranger to dinner. Before leaving him, C—— said:

"Now, what do you intend to do with this property—work it, or sell it?"

"I will develop it further and then sell it," replied the stranger.

"Just take my advice," said C——, "sell it as it is, without doing any more work on it."

The stranger disregarded this advice and put men in the shaft. Before the second shift had finished the day there was no more ore in the shaft, and, when the stranger complained, C—— said:

"I told you not to do that."

* * *

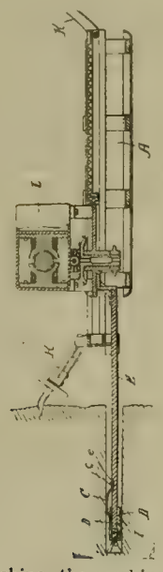
When I first went to H—— gulch, with my blankets on my back, the gulch had been extensively worked the previous two seasons and a large amount of gold obtained. There were still a few miners working along the gulch and these were doing well. The earlier miners had worked successfully, getting good pay until they reached a place where the grade of the gulch was steep and the pay poor. At the head of this steep pitch a mass of bedrock outcropped, dividing the stream into two branches. Neither of these branches contained gold in paying quantity, but above this reef the gulch became flat again; for some reason a strip of a hundred yards or more in width had not been mined. I found an old prospect hole in this flat, and, although it indicated no gold had been found, I started in at the head of the bar in the middle of the gulch and got a good

prospect in the first pan. For several days I got fair returns for my labor and at the end of the week had reached the old prospect hole. I was hard at work when I heard a footstep. Glancing up, I saw a tall, spare man, with large beard, and dressed in the rough garb of a miner. He spoke pleasantly and informed me he had sunk the hole which I had just reached in my own work. I didn't know but that he might lay claim to the ground, so I didn't magnify the results of my labor at all. I asked if he had found anything in the hole and he answered:

"Only a single color—a piece worth $1."

"Why did you not continue?" I inquired.

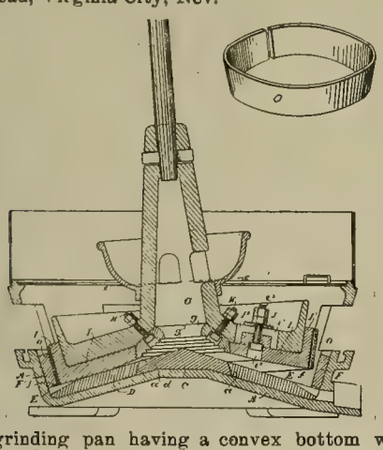
"Thought it wouldn't pay," said he; "but I hope you will do well."



I hoped so, too, and he went on down the crooked little gulch. Before nightfall I had stripped and washed the ground at the end of the hole sunk by the old man, and had gone some little distance beyond it. The ground was rich, and the single piece, worth $1, he had found, lay within a foot of a pocketfull of nuggets. I could have covered over $50 worth with my hat. The remainder of the unworked ground on this part of the gulch paid as well as any portion had paid. Some men don't know a good prospect when they see one. MINER.

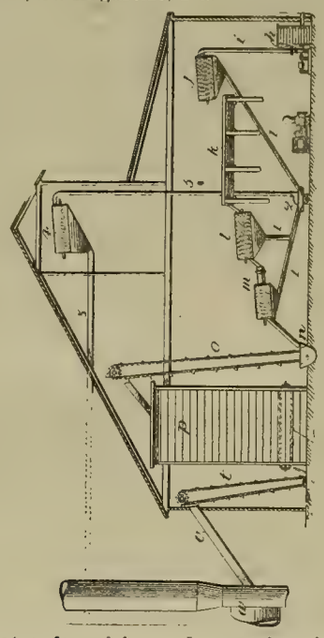
Latest Mining and Metallurgical Patents.

Patents Issued Aug. 8, 1899.



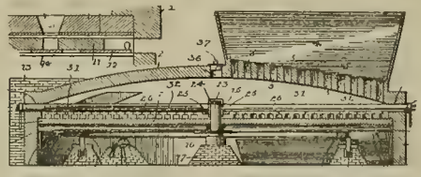
Specially Reported for the MINING AND SCIENTIFIC PRESS.

MINING MACHINE.—No. 630,388; C. W. Miller, Columbus, Ohio.



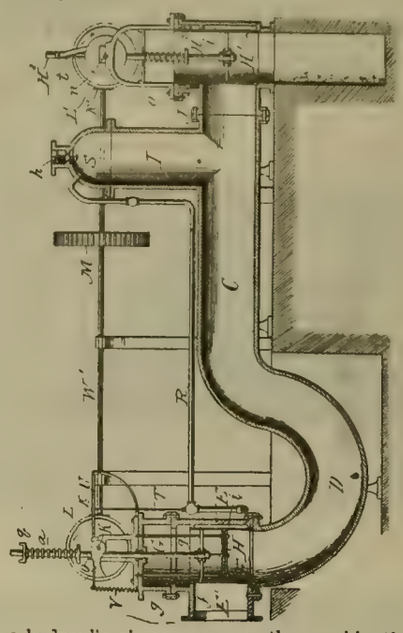
In a mining machine, the combination with a bed frame, adapted to be made stationary, carriage mounted on bed and movable longitudinally thereof, an endless cutter chain supported on the carriage, and means for moving the carriage longitudinally of the bed and for actuating cutter chain; of a vertically yielding holder, *C*, consisting of an elastic plate having one end secured to the front crosshead of the carriage, an intermediate curved or bowed portion, *c'*, adapted to contact with the adjacent horizontal wall of the kerf formed by the cutter chain, and having an oppositely curved end portion *c*, bearing upon the carriage and sliding longitudinally thereof, and means bearing against the opposite wall of the chain kerf to relieve the carriage of displacing pressure.

ROCK CRUSHER AND GRINDER.—No. 630,511, J. H Kinkead, Virginia City, Nev.



A grinding pan having a convex bottom with a flat circular central portion and inclined sides extending upwardly and outwardly at approximately right angles with the conical portion of the bottom, an independent circular central die having a conical upper surface and outwardly and downwardly diverging periphery, and a concave bottom fitting the flat central opening fitting over the periphery of the central die and locking it in place, die extending to the inner periphery of the pan and having radial grooves or channels made at intervals around the periphery, independent removable segments resting upon the periphery of die and forming a lining for the interior periphery of the pan, segments having grooves or channels made in their lower edges coincident with those of the bottom die, a circular muller having a concaved bottom of lower pitch than the bottom of the pan and adapted to contact at successive points with the pan bottom by gyrations of the muller, shoes fitting the muller consisting of a hollow central conical section fitting the corresponding hollow interior of the central portion of the muller, and bolts whereby it is secured thereto, sectional shoes fitting the sides and bottom of the remaining portion of the muller, with their inner peripheries abutting against the periphery of the hollow shoe, lugs cast upon the upper surfaces of the outer shoe sections, corresponding concavities made in the bottom of the muller to receive lugs, and bolt holes through the lugs having countersunk spaces in the bottom to receive the heads of the bolts whereby the latter are coincident with or above the bottom of the muller, and one or more split rings adapted to loosely fit between the inner pheriphery of the dies which cover the pan sides and the outer peripheries of the corresponding shoes which cover the periphery of the muller.

APPARATUS FOR MINING, TRANSPORTING, WASHING AND DRYING PEBBLE PHOSPHATE.—No. 630,395; L. R. McLain, St. Augustine, Fla.



Apparatus for mining and preparing phosphatic pebble comprising, in connection with means for mining the material, the dredge, primary pump thereon, connections by which pump takes the mined material from the sump, a pipeline leading from pump to the shore end of the apparatus, an auxiliary pump which connects with the shore end of the pipeline, and also with an upright pipe for lifting the material received through the pipeline, and apparatus at the upper end of lifting pipe which receives the material discharged from pipe, and automatically separates the pebble from the water and debris mixed with it.

ORE ROASTING FURNACE.—No. 630,510; J. F. Keiper, Everett, Wash.

An ore roasting furnace having a rotary hearth provided with a central spindle and annular supporting devices, and also provided with discharge openings extending radially from the periphery approximately to the center of the hearth, valves for controlling discharge openings and means for scraping the contents of the hearth into discharge openings. A rabble located above the hearth and having a revoluble blade carrying spindle mounted in fixed bearings, arranged approximately parallel with the surface of the hearth and adapted to be turned to remove its blades from operative relation with the surface of the hearth, and means located exteriority of the furnace for securing the spindle in its adjusted positions, to maintain the blades in the desired relation to the plane of the hearth. The rotary hearth provided with discharge openings, exposed operating lever or handle attached to the rabble spindle, and means for securing lever or handle at the desired adjustment.

AIR COMPRESSOR.—No. 630,495; R. L. Dunn, San Francisco, Cal.

In a hydraulic air compressor, the combination of a motive water pipe, connecting above with a source of water supply, and connecting below with the casing of an inlet water valve whereby the acting in it by gravity develops the kinetic energy required, a compression chamber horizontally disposed, a water trap at the inlet end of the compression chamber, a vertical extension of the compression chamber near the outlet end adapted to contain the air volume after compression; an inlet water valve between motive water pipe and the water trap, an outlet waste water discharge valve from the compression chamber, adapted, also, to admit air to the chamber, a compressed air outlet valve, valve operating mechanism for operating the inlet and outlet water valves successively and continuously, and means controlling the entrance of water to pipe whereby the amount of kinetic energy developed may be adjusted by regulating the amount of water acting in the motive water pipe.

German Zinc in America.

United States Consul C. W. Erdman at Breslau, Germany, states that upon an examination of the books of the consulate it was found the exports of zinc dust to the United States during the last seven fiscal years were as follows:

Years.	*Amount.*
1892–93	$10,533 58
1893–94	9,808 43
1894–95	37,454 40
1895–96	19,465 37
1896–97	39,024 27
1897–98	19,766 67
1898–99	41,779 39

This table shows that the export for the past fiscal year is the largest on record, not even excepting the year ended June 30, 1897, when the German manufacturers, expecting an increase in the American tariff laws, were flooding the American markets with wares of all descriptions.

IN many shops it is customary to melt babbitt metal in the smith's forge—a very wasteful and vicious method when it is considered that the forge gives too intense a heat for properly melting babbitt and that babbitt metal injures the working of the forge whenever any of the metal finds its way into and remains in the tuyeres. Lead there will effectually prevent the welding of iron as long as it is exposed to the action of the vapor of the lead. A much better way and a cheaper one is to rig up a little gas bench for the melting of small lots of babbitt. When a quantity of it is to be handled, a furnace similar to that used for melting out—and melting in, too—the lining of axle and motor boxes will do. But the gas bench is made of one or two heavy gas burners similar to those used in kitchens for cooking. They are placed in an iron bench and proper iron bearers rigged for holding the ladles in place. With this rig the heat can be regulated at will.—Iron and Steel.

ALUMINIUM is now in great demand for various purposes, such as alloys with copper, for electrical conductors, and for lithographic plates. It is superior to tin or iron for cooking utensils, and the high price of copper is causing the new metal to be used for power transmission wires. America produced 5,200,000 lbs. during 1898, being over half the total yield. The Foyers and Swiss works also show an increase, but Germany has ceased to manufacture the metal.

Proposed Removal of Arch Rock,

Written for the MINING AND SCIENTIFIC PRESS by EDWARD B. DURHAM, E. M.

Arch Rock is the largest and most prominent of a group of rocks in San Francisco harbor, that form a menace to shipping and which the United States engineers have decreed shall be removed to a depth of 30 feet below mean low water.

The group consists of Arch Rock, Shag Rock No. 1 and Shag Rock No. 2. The first two are familiar objects to all who cross the bay on the ferry to Sausalito. They are situated on a line drawn from Alcatraz to Sausalito, and almost directly in front

FIG. 1.—SOUTH SIDE OF ARCH ROCK, SAN FRANCISCO BAY.

of the Golden Gate. They are in the vicinity of the anchorage usually chosen by vessels while waiting inspection by the Government revenue and quarantine officials, as well as close to the track often taken by the ferryboats.

Not only are these rocks in the way themselves, but they are surrounded by strong tide currents, which make them still more dangerous. The tide has

FIG. 2.—EAST END OF ARCH ROCK, SAN FRANCISCO BAY.

a velocity of 5 feet per second when at the height of its ebb flow and a velocity of 3 to 4 feet per second on the flood tide. The strength of the current is apparent by the constant surf about the rock, and it is with difficulty that a landing can be made from a rowboat.

The top of Arch Rock stands 30 feet above the low water plane, at which level it is about 40 feet

FIG. 3.—NORTH SIDE OF SHAG ROCK, SAN FRANCISCO BAY.

east and west by 25 feet north and south and rectangular in shape. A little above the water line and extending 11½ feet below water is a hole, about 9 feet wide, cut through the rock from north to south, which gives it the archlike appearance from which it receives its name. This is well shown in the photographs.

Below the water line the rock gradually spreads out, until at a depth of 30 feet it has a breadth from east to west of about 300 feet and a length from north to south of 350 feet, or, taking the irregular outline into consideration, it covers an area of $1\frac{6}{10}$ acres. This rock contains 25,512 cubic yards of material, according to the United States engineers' estimate.

Shag Rock No. 1 lies north of Arch Rock and has a projection above low water of only 8 to 10 feet and an area at the low water plane about 24x30 feet. Its volume above water is small, and is well illustrated by Fig. 3, which shows the north side and one of its inhabitants for whom it is named. Under water it spreads out so that at a depth of 30 feet it measures 95 feet from N.E. to S.W. and 140 feet from N.W. to S.E. It contains 3800 cubic yards of material above this plane.

Shag Rock No. 2 is about 250 feet southeast of Shag Rock No. 1 and is unknown to most landsmen, as it is covered at low tide by 17 feet of water. But at the 30-foot plane it is 120x140 feet and covers nearly twice the area of Shag Rock No. 1. Its volume, however, is only 2979 cubic yards.

The rock in these reefs is a metamorphic sandstone and seems identical with the rock on Telegraph hill, where large quarries have been in operation for a dozen or more years. The rock, both on Telegraph hill and on Arch Rock, is broken by a series of fissures into large blocks, and these in turn are filled with minor cracks, so that, as the rock is exposed to the weather, it breaks up into irregular cubes. This easy cleavage, together with the fact that the rock is not hard to drill, will make it comparatively easy to mine.

The bids for removing these rocks were opened at noon on Aug. 12, 1899, at the Engineers' office, Flood Bldg., San Francisco. Rudolph Axemann of Los Angeles, Cal., was the lowest bidder, his figure being $253,500, or about $8 per cubic yard. The other bids were: Perrine & Buckman, San Francisco, $452,000; City St. Improvement Co., San Francisco, $277,439.40; Pacific Construction Co., San Francisco, $520,000; C. A. Warren and Healy, Tibbitts & Co., San Francisco, $317,000; California Bridge & Construction Co, San Francisco, $559,350; Christie, Low & Heyworth, Chicago, Ill., $287,379; Dunbar & Sullivan, Buffalo, N. Y., $443,840.90; A. C. Bull, Jr., Eureka, Cal., $444,000—making the range of price from $8 to $18 per cubic yard for removing the entire 32,291 cubic yards. The bids were taken under advisement by Major W. H. Heuer, who will inquire into the responsibility of the bidders and their bondsmen before awarding the contract.

Until the opening of the bids, the interesting question was: Who will be the lowest bidder? Now all interest centers on who will receive the contract and how the work will be done.

Blossom Rock, in San Francisco harbor, and Flood Rock, in New York harbor, were mined out, leaving only a thin shell, and then a giant blast blew the remaining rock into fragments, which were then removed by dredgers. Other rocks have been removed by drilling holes in the rock by machines carried on scows or on platforms set on spuds, which rested on the bottom, charging the holes with explosive and firing by electric current, thus removing slab after slab from the side of the rock, as in quarrying. The debris has to be gathered up by a dredger, as before. Other rocks have been removed by special methods designed by the contractors.

Welding by Electricity.

Some trolley companies of this country are welding their rails together by electricity—a process which has reached a high state of perfection. A welding plant of particular completeness is operated by the Lorain Steel Co. at Buffalo, N. Y.

The plant consists of five cars. One of these cars is termed the sandblast car, and it goes ahead and prepares the rail joint for the coming of the welding apparatus. This car is provided with curtains so that it can do the work of preparing the joints without annoying travel on the street. Following the sandblast car come three cars, the first of which is the welder car. Next to the welder car is the car containing a rotary transformer and then comes the motor and booster car. These three cars are coupled together. Between the welder car and the transformer car there is a sliding coupling which allows the welder car to move ahead or back several inches without any change of position of the cars following. This is so that the welder car can easily move along the distance of the joint, being made without disturbing the other two cars. This welding of joints can be made on either old or new track and on paved or unpaved streets. Where old track is to be welded it is necessary to remove about 17x22 inches of the paving in front of the rail joint so that the welder can do its work. On new track the weld may be made before the pavement is laid, or spaces of the size referred to may be left until after the joints are welded.

When a joint is to be welded a bar of steel 1x3 inches and 18 inches long, on which are three bosses (a boss being a projection of the metal on the side of a bar), is placed at each side of the rail web and the jaws of the welding machine allowed to grip it. Then a pressure of about 1400 pounds is applied by means of an hydraulic jack connected to the upper end of the welding machine. As soon as this pressure is applied the electric current is turned on. Instantly the metal between the welder jaws begins to heat. It grows brighter and brighter until a welding heat is reached, and then the current is immediately cut off; and, simultaneously, the pressure on the weld is increased to about thirty-five tons. Artificial means of cooling are immediately applied to the weld in order that the cooling may be hastened while under pressure. The comparatively cold portions of the bars about the boss prevent the more plastic metal from spreading, and the heavy pressure so confines it that there is no opportunity for coarse crystallization while cooling. The center weld is made first and then the ends of the bar are similarly treated, making three welds at each joint. This occupies about fifteen minutes, during which time the current has been on about six minutes.

As the welding bars cool they exert a most powerful influence to bring the ends of the rail together and make a perfectly tight joint. A car with emery wheels operated by a motor follows and dresses any rough portions of the joint. The welded joint offers no obstruction whatever to paving, any more than the rail web itself, as it is perfectly flat. The roadbed or ties are not disturbed, as it is not necessary to go below the rail flange in making the joint. By this process the head of the rail is heated but slightly, and thus the danger of annealing the rail head and softening it is avoided. It is conceded that a continuous rail joint should last as long as the rail itself, as their wearing qualities are the same.—Iron and Steel.

The Search for Iron Ores.

At no time in the history of the iron trade has there been so great an interest in the exploitation of deposits of iron ores in various parts of the world as at present. The Orinoco river deposits are now in a fair way to be opened by prospecting work by an American company. There is renewed activity in Cuba, and now it is stated than an English syndicate has employed some mining engineers to prospect the Australian ores. The greatest interest is now being shown in deposits which lie convenient for water transportation, although some large deposits that lie inland are being connected with shipping ports by rail, as for instance, the newly opened Swedish ores at Kiirunavaara and Luosavaara. Blast furnace establishments that are near the seacoast or that command cheap freights from the coast are especially active in the search for ore, and it would appear that the whole world is being examined for ores that will bear transportation. The newly organized Whitney Syndicate, to operate in Cape Breton, will be in the market for ores unless the explorations now in progress in that island and in Newfoundland shall prove up better than is anticipated. Two years ago there was a sensational article about the exportation of Lake ores to England and the Continent, one report going so far as to name the amount contracted for and the sellers. This story was shown to be without foundation, and doubtless originated in the fertile brain of some irresponsible reporter. There has been very little exportation of iron ore from the United States, the total amount for the eleven months ending with May, 1899, being 29,184 tons, valued at $62,931, and for the eleven months ending with May, 1898, 11,007 tons, valued at $32,976. The situation as concerns the exportation of iron ore is pretty much the same as is to be seen with anthracite coal. The Anthracite Coal Operators' Association sent its secretary, H. S. Fleming, abroad last year to study the question of sending coal to Europe, but he reported against the undertaking.

There is very little hope of anyone being able to send iron ore to Europe from this country under present conditions. What the situation would be if the proposed canal connecting the Georgian Bay with Lake Ontario should be constructed, of course no one can say. This scheme has been on the carpet for some time, but it does not appear to gather much headway. The saving in distance to the upper lakes would be between 400 and 500 miles, as, instead of going through Lake Huron, Lake St. Clair and Lake Erie, vessels would come into the Georgian Bay and by ship canal into Lake Ontario in the vicinity of Toronto, or Point Whitby. It is said that at one time, several years ago, the Whitney people contemplated the control of iron properties on the Lakes in connection with what afterwards became the Dominion Coal Company. But if any such hopes were ever entertained they seem to have been given up, and the blast furnaces to be built in Cape Breton will look elsewhere for their ores. Naturally they turn to such ores as can be secured for water transportation, and it is possible that Cuba or Venezuela will be called on for the supply. There is not enough known as to the Newfoundland ores to warrant one in saying that they can be used on a large scale by the Cape Breton furnaces.

The large iron ore properties in the United States have already passed into the hands of the great iron and steel companies, not so much, perhaps, for present as for future use, and if anyone should go into the market to-day for an iron property he would have difficulty in finding it. The recent acquirement of the Hanna interests on the Lakes by the National Steel Company is a striking illustration of the trend of events.—American Manufacturer.

Mining Summary.

ALASKA.

(Special Correspondence).—The Alaska Gold Standard G. M. Co., under the management of Capt. Chas. P. Dyer, is developing and equipping a mine twenty miles from Ketchikan and sixty miles south of Wrangle. The property comprises seventeen claims and extends from tide water up the mountain sides. A tunnel has been driven 200 feet on the ore, which is 4 feet wide. From the tunnel a shaft sinks 50 feet on the vein. A tunnel is in 50 feet at another point. The ore is sulphide of iron with large streaks of quartz, which carry free gold. The ore thus far worked ran $180 per ton. Within the last two years $25,000 has been produced from this ore by an arrastra. Last week an order was placed in San Francisco for a stamp mill and concentrators for this property. It is stated there are ores ready for milling to the value of $100,000.

Ketchikan, Aug. 5th, '99.

(Special Correspondence).—The property of the Sea Level M. Co. is twenty-four miles southeasterly from Ketchikan. The fissure vein is exposed by a system of shallow cuts and shafts every 50 feet along the strike of the ledge. From the bottom of a 50-foot vertical shaft a 115-foot crosscut has been driven. Sinking to the 100-foot level is in progress. The surface workings, it is asserted, show ore for 1300 feet. The vein exposed, it is claimed, will average 27 feet in width for 950 feet in length. The ledge is reported as containing two mineral-bearing veins—one adjacent to each wall. The material between the two is blue feldspar, carrying iron sulphides. The vein walls are mica schist. E. Lobe, W. A. Steel, J. D. Hoge, Jr., and others of Seattle are owners. A stamp mill is to be erected this fall.

Seattle, Aug. 11th, '99.

Copper ledges have been found at several places in the Chilkat mountains, back of Pyramid harbor. One of the discoverers is J. O'Mally. His ore carries gold, silver and copper. The vein is 8 inches to several feet in width.

The recent strike on the Dalton trail was a copper find near the White Horse rapids in the Copper Blow-Out district.

Nowell Bros. report the prospective sale of two Berners Bay quartz properties to English purchasers for $2,500,000. E. A. Digby is inspecting the properties.

One thousand dollars in placer gold from the Cape Nome district was brought to Seattle by Captain Harkens of the schooner Una. The gold is from one of the claims owned by Captain Harkens and partners. He does not predict anything great for the country as the season does not exceed four months. Scarcity of wood prevents winter mining and will make wintering there expensive. When he left miners were having difficulty with frozen ground. He says it is no place for a poor man and the country is staked. Up to the time of his departure, July 17, not to exceed $20,000 had been taken out. There are 6000 people at Anvil City, but many are leaving.

At Anvil City a meeting of miners was held July 15th, at which a committee was appointed to raise funds to investigate the law relating to powers of attorney and also to investigate the holding of claims by Laplanders. It is alleged that Laplanders are aliens, and as such have no right to hold mining claims in American territory. Orders have been issued and contracts let for the building of a military post at Cape Nome which will cost $16,000.

ARIZONA.

MOJAVE COUNTY.

Chloride on the 16th celebrated the completion of the Arizona & Utah Railroad. On that day a trainload of visitors left Kingman to see the last spike driven to connect the camp with the Santa Fe trunk line.

PINAL COUNTY.

J. W. Parke will put in an electric plant on the Arivaipa river to transmit 200 H. P. electric power fifteen miles to the Mammoth mine. The mill is now operating fifty stamps; forty more are to be added.

YAVAPAI COUNTY.

Phœnix *Herald*: The Whipsaw copper claims in the Castle Creek district have been sold in Phœnix. It is said the price was $30,000.

Journal-Miner: A strike of rich copper sulphurets was made last week in the News Co.'s property south of Jerome, operated by Owen & Van Zandt. The property is equipped with a steam hoist. The parties having a bond on the property have taken up the bond. The Decatur Co., near Jerome, last week struck a body of copper sulphuret ore. These finds demonstrate that the Jerome ore belt extends in a southerly direction. The News and Decatur properties are between Jerome and the Copper Chief mine.

Prescott *Courier*: J. Milligan of Colorado, who owns properties east of Cherry Creek station, says a copper-gold belt runs through that section, and has shipped to the sampler a ton of copper, silver and lead ore. A previous shipment carried 20% copper. One of the claims of his group carries 147 ounces of silver per ton and 25% copper. The property is between Copper mountain and the United Verde mines.——Eastern parties have bonded mines near Thumb Butte, four miles west of Prescott, from Mr. Johnson, for $10,000.

YUMA COUNTY.

Twenty placer claims have recently been located and filed upon along the Colorado river above Yuma.

The Harqua Hala G. M. Co.'s property was sold on the 14th inst. at auction. The sale comprised mines, mill site, pumping plant, 40-stamp mill, cyanide plant, engines, boilers, machinery fixed and movable, and stock of merchandise at Harqua Hala. The property was bought by Mr. Hubbard of San Bernardino, Cal., one of the original owners of the property.

CALIFORNIA.

Amador.

New pottery works are to be established at Carbondale, where there is a bed of pottery clay.

The Mutual Co., which recently purchased the Fernando ranch, on the Amador road, for $60,000, is operating under the management of S. R. Porter of the Ballol. Grading for a three-compartment shaft, to sink 2500 feet, is in progress.

The crushing of 100 tons of Central Eureka ore at the Zelle mill in Jackson is not completed, but it is said to be rich.

It is reported at Plymouth that Hayward & Lane will resume operations at the Hazard mine, one and one-half miles north of Amador City.

The shaft at the Lincoln mine at Sutter Creek is down 1070 feet in hard rock. It is the intention to sink to the 1500 level, with a 100 sump, when crosscutting to the vein will begin. A west crosscut is being run on the 500 level for the foot wall vein encountered on the 300 level. In a drift on the 500 level the vein is 8 feet wide, runs $2 to $3 per ton and contains 3% sulphurets which assay $75 to $100 per ton. Twenty-four men are on the payroll.

The three-compartment Emmerson shaft of the Wildman-Mahoney mine, started in December, 1897, is down 555 feet. Machine drills are now in use. It is proposed to sink 3000 feet, but at the 1400 level crosscuts will be run. The Wildman shaft is down 1300 feet. No. 10 level is being opened from the Mahoney shaft and sinking will be resumed. These mines have eighty stamps.

Amador *Record*: The Poker Bill mine, opposite West Point, is doing well. A shipment of two and one-half tons of ore netted $602. Another shipment of higher grade has been made. The second shipment is said to have been solid metal. Charles Zavella and Frank Stewart are the owners.

Sutter Creek *Record*: At the Ballol mine sinking is still in progress. The shaft is down 400 feet and will be sunk 200 feet deeper before the mill is started. Seventeen men are on the payroll.

Butte.

Flagler & Taber of San Francisco are developing the Wagner gravel mine, at Morris ravine.

Calaveras.

At the Melones on Carson hill a 10-ton cyanide plant has been installed to determine the practicability of dispensing with concentration and treating the pulp as it comes from the plates by the cyanide process.

In the Swank land case at Copperopolis Registrar Maxey decided that the ground known as the Ida Elenore and Mosier placer claims, is agricultural land and Agent Pryor claims that they are mineral lands. The latter states that as the case was tried before and it was declared to be mineral land, that when the Government ordered further testimony to be taken that the Commissioner declared the burden of the proof was on the agricultural claimant and that the mineral claimants had shown its mineral character by a preponderance of evidence. The case will go to the Land Commissioner at Washington.

San Andreas *Prospect*: The Big Horn mine on San Domingo is being crosscut by a tunnel.

Angels *Echo*: The Mount Echo M. & D. Co.'s mine has been sold to James Burke by Frates, Newman & Bagley.

San Andreas *Citizen*: The Thorpe mine, near Fourth Crossing, which for some time has been under bond to the Thorpe Gold Mining Syndicate, has been closed down and the bond returned to the Thorpe Gold Mining Co. The contract demanded that they should sink 500 feet on the lode during the year, which they failed to do. They put in heavy machinery and, including the forfeit of $25,000, they have spent over $125,000. They have put in a 3-compartment shaft to the depth of 500 feet, 200 feet above the depth reached by the old company. The rest of the time was put in stoping the upper levels, upon which the mill has been working since it went into operation. The old company has reappointed L. Allgewahr superintendent, and it is reported that work on the property will not be suspended. ——Exploration work has been pushed on the Veritas mine at San Andreas by Supt. Clark. Several strikes have been made.——Three shifts are sinking the shaft on the Commodore mine, near San Andreas, and an average of 5 feet a day is made.——The Fort Wayne stockholders have, through F. J. Solinsky, paid all claims against the company contracted by J. F. Clapp, and work is to be resumed, with W. Knight as superintendent.

El Dorado.

The Indian Diggings are being opened by Hayward & Lane. They are using 800 inches of water. A pit 700 feet long and over 100 feet deep at the upper end has been piped out to carry the flume into the pay dirt back in the hill. They have 30 feet of gold bearing deposit at the bottom. Most of the deposit being piped is a loam that goes off rapidly, but there are occasional bunches of lava cement that have to be blasted. They are using water six hours per day as the supply is not equal to all their requirements. Oliver Ball is in charge of the work.

Amador *Record*: The German mine has closed down on account of scarcity of water. ——W. Biggs and others have leased the Belmocido mine.——J. G. Mayer & Bro. have purchased the North Star claim from C. Padilla and T. Franklin and they are now unwatering the same.——The New Montezuma Mining Co. have bonded the Red Cloud location from A. W. Harvey, it being the northern extension of the Montezuma.——Work on the old Montezuma shaft is to begin in a few days. A hoisting engine is on the way. This shaft has been flooded since 1871. The water is 75 feet from the surface. At this point a few days ago a sample of ore was assayed, returning $148.82 per ton.

Placerville *Republican*: The Pacific gravel mine is south of Fair Play and consists of 60 acres of land on the Coyoteville channel, between Spanish creek and Cedar creek. Their main tunnel is in 268 feet and several cross drifts have been run in pay gravel. A space 30 by 90 feet has been worked and paid $4 a day to the man. The gravel is cemented and will require a mill. The owners are Sacramento people.——The El Dorado W. & D. G. M. Co. are reopening the old Iowa canal, which heads in North Long canyon and takes up the waters of its three branches. There are 14 miles of ditch to be opened up.

Placerville *Nugget*: There is a large force working at the Blue Gouge mine near Sly Park. Mr. Bind is Supt.

Inyo.

Bishop *Register*: G. L. Albright has built a 5-stamp mill for working Poleta ore, two miles north of east of Bishop station at the foot of Silver canyon. Two thousand feet of flume, giving 125 feet fall, will be completed before the mill can start.

Kern.

Coal is reported fifteen miles west of Randsburg. It is lignite and is said to burn freely, with a good heat.

Los Angeles *Times*: A. W. Collins, president of the Eureka G. M. & M. Co. of Randsburg, which owns the Black Hawk mines in Rand district, reports that the cyanide plant at Cuddyback lake will be moved to the Black Hawk group, where there are 1000 tons of tailings.——It is reported at Randsburg that a new vein of ore has been struck in the Hercules level of the Yellow Aster mines, 60 feet wide, which mills $12 to $20 per ton.

Madera.

(Special Correspondence). — The purchase price of the Standard and Contention claims, near Central station, has been paid in cash—$8000 for the former and $3000 for the latter claim. They are bought by Messrs. Kiefsaver, Struntz and Lindsey, who have just completed a 15 H. P. hoist on the Standard and have finished the grading for a mill with concentrators to be placed at the nearest point on Fine Gold creek.

The Lily mine has recently sunk 150 feet and is engaged in sinking an additional 150 feet when drifts will be run. About twenty men are at work on the pipe line to convey water from Fine Gold creek. It is taken out at the Sulphur springs.

The Waterloo is working a full force of men.

The grading has been done for the smelter at Madera, a large quantity of brick has been delivered at the site and building will commence in a few days.

Gold, Aug. 15th, '99.

Mariposa.

Copper mining is active along the belt extending southerly from Hunter's valley through White Rock into Madera county. Eighty tons of ore were recently shipped from the Walker mine in White Rock valley which netted $54 per ton.

Nevada.

The Champion M. Co. will build a new hoist on the Merrifield mine, near Nevada City.

Nevada City *Herald*: It is known that the ledges now being worked by the Empire, W. Y. O. D. and Pennsylvania Co's. run under and pitch toward the town of Grass Valley, and representatives of the Empire and Pennsylvania mines have been endeavoring to buy mineral rights of the individual owners who hold the continuation of these ledges. The Empire Co. has bought the Crown Point and Rodda's property. The principal owners of this property are F. Trevillian, A. Henderson, M. Provine, J. Williams, C. Barker, H. Champion and others. They have formed a combine and the whole tract will be offered to the Empire Co. If it can be arranged, the ledges will be sold separately—the Pennsylvania ledge to the Pennsylvania Co., the W. Y. O. D. to the Grass Valley Exploration Co. and the Empire ledge to the Empire Co.

Grass Valley *Union*: At the Malakoff gravel mine, near North Bloomfield, the drift method of operating gives indications of success, as the company is in good gravel. The pay dirt was struck below the tunnel, bedrock having pitched downward. It is reported that a recent washing averaged $5 per car.

Placer.

The directors of the Morning Star mine, at Iowa Hill, at a recent meeting, declared the regular monthly dividend of $2 a share.

Auburn *Herald*: The Jupiter Con. has 2 feet of gravel which prospects well.——The tunnel at the Red Point mine, near Damascus, is in two and three-fourths miles. The loaded cars run out by gravity and are drawn back by horses. The pay is chiefly in gravel on bedrock, and sometimes 2 or 3 feet in the bedrock itself. The channel is winding and crooked and was passed in opening the mine, owing to a sharp curve, although within 12 feet of the tunnel, which was run 1500 feet past it. Seventy-five men are employed under Supt. J. A. Ferguson.——A New York company has located a ledge below the Pioneer mine, near Damascus, and named it the Southern Cross. R. J. Trimble is in charge. The Bellevue Con. M. Co. has been incorporated by F. E. Brye, P. S. Lozano, A. L. Smith, E. L. Hawk and S. Bartlett.

Colfax *Sentinel*: Development is in progress at the Jupiter gravel mine, above the Morning Star, near Iowa Hill. With a 12 H. P. engine and hoist, an incline of 45° has been sunk 350 feet to the channel. Recently $200 in gold was washed from gravel taken out in crosscutting the channel. Twelve men are employed. C. A. Wickman is Supt. and F. H. Harvey of Galt is consulting engineer.——L. L. Chamberlain of Auburn has given a working bond on the Dardanelles drift mine, near Forest Hill, to W. McDonald, J. Marchant, A. McDonald and F. E. Vennewitz. The mine has a 5-stamp mill. The lessees have a two years' bond with the privilege of purchasing the property for $15,000.

Plumas.

Marysville *Appeal*: J. Smith, Supt. of the Golden Ancient mine on Bear creek, reports that the work of sinking the shaft has been suspended for the season, unless the company decides to put in a hoist, as the water that has been furnishing the power is exhausted. They are down 275 feet.

San Diego.

For years dry washers have taken gold from the gravels of Picacho basin. The gold district covers an area of twenty-five square miles. All of this is not gold bearing but the beds of the gulches within this area and the gravel of the plateaus all contain fine gold. The workmen are mostly Mexicans who are satisfied with small returns. In the southern half of this area and extending from the banks of the Colorado river back for two miles or more to the lava beds are found numerous veins and large zones or lodes which are auriferous. Some of these are over 100 feet in width and can be seen outcropping for several thousand feet. In a portion of these the gold is alloyed with silver to such an extent that the bullion is worth only $10 to $12 per ounce. This portion of the district is known as the White Gold basin. The northern half is somewhat like that described but the ore deposits are smaller and less prominent. In this section there are numerous white quartz veins running irregularly through the country but these have not been found to contain gold. The ore deposits occur as fissured zones in which the country rock has been altered to ore. Silica in these deposits is not abundant and the values are chiefly in gold.

The American Girl M. Co. has incorporated with H. H. Markham as Pres.; T. Johnson, Vice-Pres.; G. H. Coffin, Sec.; F. S. Daggett, Treas. The company owns a group of claims in the central portion of the Cargo Muchacho range, five miles from Ogilby station. These mines resemble those at Hedges, four miles farther north. The principal claim is the American Girl.

Yuma *Sentinel*: T. W. Brooks has been to the Potholes district, above Yuma on the Colorado river. He is president of the Colorado River Gold Dredging Co., which proposes to operate in that vicinity.——At the Colorado mine, owned by A. Modesti and F. Avila, twenty-five men are at work and $6000 worth of ore will be shipped this month.

San Mateo.

On the coast below Half Moon bay E. M. Hoagland has a 600-foot well down, with every indication of oil. About $150,000 has been spent in oil prospecting in that locality.

Santa Barbara.

Oregon G. M. & M. Co. of Santa Barbara has been incorporated; capital $100,000; R. B., V. E. and M. E. Trace, L. Rethune, W. J. Bradley.

Shasta.

The reported strike in the Oro Fino mine was made at a depth of 75 feet, 16 feet below the floor of a 200-foot tunnel.

Redding *Searchlight*: A strike on new ground is reported by C. Hartman, owner of the Tarantula mine, near Iron mountain. A crosscut tunnel 115 feet long tapped a 15-inch vein at a depth of 60 feet that assays $300 per ton in gold. He will run his arrastra on this ore while doing development work with the view of building a mill. In the old works is a body of ore ranging from $7 to $30 per ton.——A San Francisco company is running ten stamps on the Gopher mine. The rock is from a large porphyry dyke which carries gold in quartz seams.

Redding *Searchlight*: At the Boulders Mining Co., which recently purchased the Boulders property near Castella for $75,000, pumps and a hoist are to be installed. G. W. Carr is superintendent.

Sierra.

G. W. Parsons, at the Alta mine, Forest, has established the first cyanide plant in that section.

Dr. Keith has finished surveying his Phœnix mine at Sierra City.

Employes of the Mountain mine have filed liens for $6000, unpaid labor claims thereon. G. M. Pinney, the Supt., expects to satisfactorily adjust matters.

The Mammoth Springs drift mine, near Forest City, has been sold to W. L. Ducey by G. R. Tuttle and J. W. Maguire. The gravel has improved in quality and more extensive operations will be carried on. At Alleghany City the Kenton and Alta mines are running. At Forest the Harper claim has rich ore and the gravel properties are looking well.

C. C. Weisenburger and T. Jewett, of Grass Valley, have a 3-stamp cyanide mill at the Alta mine, near Alleghany.

Grass Valley *Union*: James Arnott Jr. reports that at the Rocky Peak mine they have struck gravel.

Downieville *Messenger*: At the Mountain mine an attachment has been put on the property by the laborers. The amount due is about $6000. The men attached the bullion, amounting to $1800, and also filed liens on the property. The Mountain View M. Co. is a consolidation of the '76 and Pennsylvania claims, near Forest City, and was recently incorporated. The company is running a tunnel to strike gravel at the end of 200 feet from the point where they are now working.——The Mammoth Springs drift mine, near Forest City, was sold recently to W. L. Ducey by G. B. Tuttle and J. M. Maguire. The channel is 300 feet wide and extends one and one-half miles in length.

Siskiyou.

The Little Tiger Co., which started with

two claims near Yreka, has purchased five others, including a mill site, with a good water supply and several thousand dollars' worth of timber. The company has secured long options on five more claims.

W. H. Crooker has bonded for Eastern parties the Reeder & Brown group in Fool's Paradise district, on Shasta river, half way between Hawkinsville and Klamath river, and they are to be prospected with a stamp mill.

The Salmon River Hydraulic M. Co. has suspended operations on account of scarcity of water.

The Mabel quartz mine, in the ridge between Oak Bar and Scott Bar, is building a sawmill, and a quartz mill is to be brought from Ashland.

Mr. Garret, at Hamburgh Bar, has made a strike and is moving his derrick to the newly discovered channel.

The American Bar mine, on Klamath river, below Hornbrook, is being worked with fifty men, running day and night.

The Schroeder quartz mine, at Deadwood, worked by the Canadian Co., is yielding good pay. Twenty-five men are employed.

Sonoma.

The Great Eastern quicksilver mine, four miles north of Guerneville, is producing more than at any former time.

In Pine Flat district a ten-ton furnace has been completed at the Cloverdale mine, and the Boston will soon become a producer.

It is reported that a company has been organized to operate the Oakland mine, on Sulphur creek.

Most of the quicksilver mines in this county occur in serpentine. The quicksilver mining industry was at one time active in Sonoma, but the mines have been idle for a long time until recently.

Tuolumne.

The mill at the Shawmut mine, near Jacksonville, was struck by lightning recently and burned.

Sonora *Union-Democrat*: The Crystalline mine, two miles northwest of Jamestown, is bonded to a Scotch company. The shaft is being sunk without reference to the vein, but at a uniform angle. The shaft is down 250 feet. A tunnel is being run from the west which will tap the vein at a depth of 300 feet. The mill is nearly completed. Battery blocks for twenty stamps have been put in, though the mill will start with ten stamps of 900 pounds each. Later ten will be added.——The Punch Bowl gravel mine, two miles below Rawhide, is being worked by C. E. Shafer. On the north side of the mountain an incline shaft has been sunk 220 feet, where water was encountered. This shaft is intended to strike the main channel. Before this is accomplished arrangements must be made for a pumping plant.——The F. B. Gandy mine, half a mile north of the Tarantula mine on the east vein of the lode, prospects well in the slate. A tunnel is being run to tap the vein.

Sonora *Independent*: Rich rock is being taken from the 100-foot level of the Toledo mine, southwest of Tuttletown, and west of Mormon creek. Some of the specimens were exhibited in Sonora this week. This mine produces arsenical sulphides rich in gold.——H. Nelson is developing a copper prospect on the Ohio ranch, west of Jamestown, called the May Day mine. There are three parallel veins. Sinking is in progress north of the old shaft on a new vein.——At the Draper mine, near Soulsbyville, Supt. G. T. Dyer reports the mine dry and the pumps working. Two shifts are working.

Trinity.

Weaverville *Journal*: The Unity Co.'s mining property in Minersville, owned by an Eastern company, has been equipped with hydraulic mining plant and will be ready for work when the rainy season begins. A dam has been built across the east branch of Stuart's Fork, 100 yards in length. Five miles of ditch will convey water to the mine.

Yuba.

Grass Valley *Union*: A mill will be erected at the Blue Point gravel mine, near Smartsville. W. Kilman and F. Wright will open the property and $20,000 will be spent developing it.

COLORADO.

ARAPAHOE COUNTY.

The Denver Smelting & Mining Co. was incorporated at Denver on the 11th inst. It is stated that the company will build a smelter in Denver to compete with the trust; capital, $1,000,000. The incorporators are N. M. Joralmon, F. W. Crocker, Denver; N. Tooker, New York; T. Scattergood, Philadephia; I. Champlain, Providence, R. I.

BOULDER COUNTY.

The pyritic smelter at Ward is reported working satisfactorily.

Boulder *News*: G. Teal, Mgr. of the Pennsylvania group at Sunnyside, has ordered the machinery for a stamp mill. He has been developing for two years and has reached a depth of 300 feet. Large bodies of ore are blocked out, and twenty men employed.——Spence and Booth have taken the Silent Friend and are putting in a new compressor. They will sink 400 feet.——J. Luxon, Supt. of the Ermine group, has let a contract to sink 100 feet.——The Horsfal employs eighteen men and ships sixty tons per week to the Culbertson mill. ——The old Slide gives employment to forty leasers, and on the Cash there are eighteen. ——The new Cold Springs Co. has thirty-five men employed, and this week a compressor was started on the tunnel being driven to cut the leads.——At Wall Street the shaft on the Garland is being sunk to 700 feet and the Hastings tunnel is being driven 700 feet to connect with the bottom of the shaft. The vein in the shaft is 2 to 4 feet wide and a contract has been made to furnish the Culbertson mill 200 tons of ore. Supt. J. Tergarden of the Wood Mountain properties has contracted to furnish one carload of ore a day to the same mill.

Ward *Miner*: Since the Muldoon Co. started work they have driven the Deliverance tunnel 10 feet; the breast of the tunnel is mineralized and will return $8 per ton.

CHAFFEE COUNTY.

In this county J. C. Baird has a copper mine which carries nickel, gold, silver and 14% copper. He will put in a pump and open up the ore. The group embraces the Silver Coin, Humboldt and Tamarack.

CLEAR CREEK COUNTY.

Central City *Register-Call*: Goodyear & Miller are working the Lee or Ross lode at Yankee Hill and are taking out ore which is being treated at the Lee mill.——Joyce & Utley are working their Last Hope property through a tunnel, which is in 200 feet. They have 2 to 3 feet of milling ore.——Gow Bros. are working the Puritan on Chesapeake mountain and are taking out ore worth $100 per ton.——C. Dow is running a tunnel into Chesapeake mountain near St. Mary's lake and has struck rich ore, reported to be tellurium.

GILPIN COUNTY.

Following is a list of the mills running in Black Hawk, with the number of stamps dropping:

Mill.	Stamps—Slow drop.	Fast drop.
Cashier	..	10
Hidden Treasure	75	10
Mead	40	..
Eagle	..	35
Polar Star	40	..
Bobtail	75	..
Gilpin	50	..
Randolph	40	..
New York	50	20
Penn	35	10
Iron City	..	25
Totals	405	110

A total of 515 stamps, of which the slow drop are supposed to treat an average of one ton per stamp each day, while the fast drop stamps are treating from two tons upwards to the stamp, the total tonnage being 750 tons. In addition, the State Ore and Chamberlain sampling works are treating 125 tons per day and the Rocky Mountain concentrator 40 tons per day, making a total of over 900 tons of ore daily treated at Black Hawk, and this does not vary much at any time of the year. The Perigo mill in Gamble gulch is crushing 100 tons per day, and the Rollins and Daisy mills in the same gulch are running, which, with the mills at Gilpin camp, brings the total daily tonnage of the county up to 1050 tons. The Cashier mill is running on ore from the East Whiting mine on Gunnell hill, handling 30 tons per day.

Central City *Register-Call*: W. C. Stanley has a lease on the War Eagle lode on War Eagle hill and is taking out ore which will be crushed in his new stamp mill in Lump gulch. ——L. Essman has given an option on his Last Chance lode to J. Kemp of Eldora.——E. W. Morse is in 125 feet in the tunnel he is driving on the Gold Anchor lode, and reports a body of ore that averages $10.

GUNNISON COUNTY.

(Special Correspondence).—R. L. Hamill has purchased machinery for the Lucky Strike M. Co., to be erected on the Lucky Strike mine. Water nearly fills the shaft at present. When the water is out sinking to 500 feet and running drifts on the vein will commence. The ore is free milling at present depth, and as there is little or no iron sulphides it will likely continue to be so. The vein is 2 feet wide, a dark bluish quartz, resembling agatized quartz. Mill runs made in the early history of the mine were said to be $100 per ton. It is not far from the Mineral Hill mill. The property is owned by New York people.

Gunnison, Colo., Aug. 14th, '99.

HINSDALE COUNTY.

Lake City *Times*: F. Hill, who is working the George III at Carson, has opened up rich ore.——Work on the Vermont tunnel has been resumed under the management of D. McCafferty, who has taken the contract to complete the work.

LAKE COUNTY.

Leadville *Miner*: The continued idleness of the trust smelters outside of Leadville is working a hardship on miners and operators of this district. The zinc and steel-iron shipments, together with the ore taken by the Philadelphia and other independent smelters and two local trust smelters, makes the present output 1800 tons per day, but it could be easily made 3000. The Arkansas Valley works are receiving 700 tons.——The Lillian gold mine on Printer Boy hill is making heavy shipments, the Vaughn, Smith & Bray, Davis & Foutz and Chamberlain leases being the principal outputters of high-grade gold-lead ores.——The new Northern is sending 120 tons of silver-iron to the Arkansas Valley and Durango trust plants daily; the Louisville is sending 50 tons per day; the Dollie B. gold mines, under the superintendency of T. Simpson, is sending 50 tons a day.——The Philadelphia smelter will draw on this market, particularly for sulphides. The works will be enlarged.

MONTROSE COUNTY.

The La Sal Copper M. Co. is going to build a 100-ton reduction works in Paradox valley, and a wagon road to Cisco, Utah. W. J. Cashin is Mgr.

For several months the La Sal Copper M. Co. has employed thirty-six teams hauling ore to Placerville. The company has run a crosscut connecting with the shaft for ventilation. The La Sal Co. owns twelve claims, but the principal work has been done on the Angell and Red Cliff. The veins are fissures cutting through the sandstone and traceable on the surface for miles. The Angell and Red Cliff cross each other and at the intersection a shaft has been sunk 220 feet, from which levels have been run in both directions at intervals of 50 feet. The ore shipped came from these workings and has yielded a good profit. On the dumps and in the bins are 1500 tons of lower grade. Tests of this grade of ore show an average value of $35 per ton, which will not stand transportation by wagon seventy miles to the railroad. The tunnel is in 500 feet and will reach the shaft in 200 feet further. The shaft will have to be sunk 50 feet to make the connection, when the ore will be taken out through the tunnel. A compressor plant will be installed. The company has bought a smelter and had a building erected, but after a number of tests decided to treat the low-grade ore by the leaching process. The company owns a water power, carrying the water in pipes 3000 feet, securing a fall of 100 feet. A wheel has been installed to furnish power. The vein is 4 feet wide and carries good values in copper throughout, with some silver. In all of the workings it maintains its width.

In the claims of Galloway Bros. & Hamilton, on the north side of the valley, the Angell vein outcrops through the sandstone bluffs and the ore is of the same character as that in the workings of the La Sal. A short drift has been run on the vein. A carload of first-class ore has been shipped which ran more than $160 to the ton, and several tons of second-class ore are now lying on the dump. The Sunrise claim is being developed, but no shipments made at present.

SAN MIGUEL COUNTY.

The tracks at Ophir Loop are crowded with loaded cars waiting for the smelters to resume. The most serious effect resulted from the closing of the Carribeau. The mine was operated for several weeks after the strike commenced, but closed, throwing 70 employes of the mine and mill out of work. The Silver Bell and Butler are running, but will soon shut down, unless the smelters resume.

SUMMIT COUNTY.

The three dredgers of the North American Gold Dredging Co. are now in successful operation near Breckenridge, the hydraulic elevators handling 1000 cubic yards every twenty-four hours.

Breckenridge *Journal*: A number of the old mines of this county about Breckenridge are being reopened. During July the quartz mines of Breckenridge are reported to have produced $22,000, mostly the work of leasers. Including placer operations, the output was $50,000.

TELLER COUNTY.

The new machinery is in place at the Isabella and sinking will be resumed. The mine is as well equipped as any in the district. It is learned that the production of the 11th level is being maintained, the ore is of good grade, not the high-grade mineral produced in the level above.

In the District Court Judge Stimson has decided that the Independence Town & Mining Co. could not take ore from the disputed ground between that company and that of the Wilson Creek Con. M. & M. Co. It is the first decision against the legality of the title to the Hull City placer. The Wilson Creek Con. Co. is also restrained from extracting or mining any ore from the ground in dispute.

Cripple Creek *Times*: The Chapin Co. have the property of the Smith-Moffat Co. under bond and lease and contemplate building a sampler to handle the ore mined before it goes to the mill.

Denver *Republican*: In the Doctor-Jack Pot apex controversy, the concensus of opinion in Cripple Creek is that the Creston M. Co. is in no danger of being interfered with in its work of extracting ore from the Jack Pot. An agreement had been entered into between the officers of the Jack Pot and C. J. Perkins, attorney for the Doctor people, by which a joint survey was to be made of the two properties. The Jack Pot surveyors appeared at the Doctor mine with their instruments, were lowered to the first level, and were commencing work when they were ordered off the property by the lessees. The reason given was that the lessees did not enter into the agreement. The Doctor surveyors did not put in an appearance at the Jack Pot. It is stated there are two separate and well defined veins in this property. As a matter of fact, the so-called Doctor vein, where it has been proved up in the Jack Pot, is better defined than the Jack Pot vein, although it fails to carry values. The old Jack Pot shaft was sunk on an incline to a depth of 278 feet. At a depth of 80 feet the Doctor vein was cut in the shaft, and was followed on its dip to the depth stated. The bottom of the shaft was found by survey to be 28 feet over the Work Co.'s line. A crosscut was started from the bottom of the shaft, which was driven 55 feet, when the Jack Pot chute was encountered. Having determined the trend of the ore body, the Jack Pot lessees opened it on their own ground. A drift was started from the bottom of the shaft on the old vein and was driven back to the Jack Pot line. By survey it was estimated that 65 feet of crosscutting along the line would cut the chute. The two veins were thought to be parallel, but subsequent work has proved them to diverge as they go north. The crosscut was driven 75 feet before the ore shoot was cut. All the drifting upon the old vein has not resulted in a pound of ore, while developments in the other shoot have exposed very rich ore. At a depth of 280 feet the shoot was cut in the Boyd shaft, on the Morning Glory. At a depth of 383 feet in the Jack Pot the shoot was found 12 feet west of the new shaft. Between the two Jack Pot levels run from the straight shaft there is a difference of a little more than 30 feet between the points at which the ore was found. Allowing that the dip of the shoot is 30 feet in every 100, and that it keeps its course to the surface, its apex is well within the Jack Pot claim. The wash is deep and no work has ever been done to prove up the apex.

IDAHO.

The Salmon and Clearwater placer mines in Idaho, according to Wells - Fargo Express Company's receipts, yielded in gold dust and nuggets from $38,000,000 to $40,000,000 between 1860 and 1864. This district is now being searched for the veins from which the gold in the placers came, and important discoveries made.

ADA COUNTY.

Deposits of gold at the U. S. assay office at Boise have this year been running above the record of any previous season. For the week ending Aug. 12th the amount was $71,434. The total for the corresponding week last year was $31,769.

BOISE COUNTY.

By the caving of the shaft of the Wolverine mine at Banner, five pumps, three cages, tools and iron pipe were lost, worth in the aggregate $5000.

CANYON COUNTY.

Gov. Adams and others of Denver, Colo., will run an 800-foot tunnel to turn the Deadwood fork of the Payette river one and a half miles to work the gold gravel. The enterprise will cost $30,000.

Boise *Statesman*: A. B. and D. G. Caswell, discoverers of Thunder mountain, have taken more than 200 ounces of gold from their claims this season. They have twelve claims, fourteen acres of which is soft rock, which, they say, averages $12 per ton in gold. The air slacks off 5 feet deep of this formation each year. One hundred and fifty locations were made this year, some of which are paying. The gold-bearing territory in the vicinity of the Caswell claims is four miles square. At a recent meeting a district was organized and W. Richey made recorder.

IDAHO COUNTY.

(Special Correspondence). — The Central Idaho Gold Dredging Co. have built a new dredger, which is operating at Elk City, on Red river. Its working capacity is 1500 cubic yards per day. In the main it is of the Bucyrus type, but has a gold-saving feature, designed by Howe & Juessen of Spokane, Wash., consisting of a system of adjustable tables, capable of being adjusted to the quantity and character of the material handled. There are 1280 acres of ground in the tract, the average depth of the material being 8 feet.

Elk City, Aug. 14th, '99.

Litigation between owners of the Black Warrior mine, in the Seven Devils, and the owners of the Decorah, has been settled, and it is reported the Boston & Idaho Copper Co. of Boston has bought the two properties. Mr. Hancock of Boston is Mgr. of the purchasing company.

OWYHEE COUNTY.

J. B. Irvin, Gen. Mgr. War Eagle Tunnel & Development Co., says he will start work next week on a tunnel through War Eagle mountain from Sinker creek.

The eighth annual report of the De Lamar Mining Co., Ltd., has been issued for the year ending March 31, 1899. The revenue for the period amounted to £15,345 3s 11d. The directors paid from this amount £10,000 as a dividend of 6d per share for the year, and £1832 17s 11d were paid out for royalties for operating under a patented process; £2273 11s 6d were paid in completing air compressor and tailings plants. The report of Manager D. B. Huntley states that 51,527 wet and 46,333 dry tons were treated assaying $10.52 gold and $1.30 silver. Of this amount assays of tailings show that 70.47% were saved, though, according to bullion returns, the actual saving was 72.73%. Of shipping ore sent to smelters there were produced 34.124 tons, yielding $13,420.60, or $393.28 per ton. The total product of the mine was £90,777 11s 10d at a cost of £74,389 13s 3d. The cost per ton including development work and other expenses was $7.86, as compared with $9.53 and $11.14 in two preceding years. To reduce expense of treatment and to profitably treat the ore, which is decreasing in value, additions were made to the leaching and tailings plants. Vigorous prospecting has been prosecuted during the year, resulting in some discoveries. The manager has been directed to look for another property, which led Mr. Huntley to investigate the Buffalo Hump country. By comparison the figures of cost per ton in the report may seem excessive to those who are more favorably located, but the isolated position of this property and the excessive cost of supplies and transportation in a measure accounts for this.

SHOSHONE COUNTY.

In the Cœur d'Alenes mine managers now have opportunity to employ all the men they need and everything is running smoothly. Supt. McDonald of the Helena-Frisco reports that the mine is producing as much ore per man as at any time in its history, and that everything is in better shape than ever before. G. Bixby, formerly of Owyhee county, is general foreman of the Helena-Frisco.

MICHIGAN.

HOUGHTON COUNTY.

Rich copper is being secured in twelve and thirteen levels south of No. 3 shaft at North Tamarack, some rock running 15% copper.

MISSOURI.

The miners at a recent meeting at Joplin fixed the minimum price for zinc ore containing 63% metal at $46 per ton, and for every 1% less of metal in ore a reduction of $1 per ton.

Iron and Steel: There is no surplus zinc ore in Joplin district. All of the product is sold or contracted, and unless the association authorizes the resumption of night shifts there is likely to be a scarcity.

MONTANA.

MADISON COUNTY.

The smelter at Twin Bridges will be in operation Oct. 1st, '99.

JEFFERSON COUNTY.

The Katie smelter will blow in Oct. 1st.

SILVER BOW COUNTY.

The suit between the Montana Ore Pur-

chasing Co. and the Boston & Montana Co. is in progress in Butte before Judge Clancy. The Montana Ore Purchasing Co. owns a portion of the Johnstown claim and brought the suit to determine its right to the dip of veins from the Johnstown under the Pennsylvania, which the Montana Ore Purchasing Co. claims have their apexes in that part of the Jownstown which it owns. It is a question of extralateral rights. When the suit was filed heavy damages were asked, but this part of the case has been dismissed, leaving only the question of equity to be determined by the court. The Boston & Montana Co. in its answer denies the allegations in the complaint and denies that any of the veins or lodes beneath the surface of the Pennsylvania belong to the plaintiff, and claims the ownership of all such veins and lodes. It is said that in the disputed ground there are veins or ledges of ore carrying deposits of minerals separated by bodies of rock mineralized so slightly as to be virtually barren, and it is supposed that the contest will be between the zone theory and the single ledge principle. The zone theory is that a belt or strip mineralized as stated is to be regarded as a single lode, however many different veins and ledges it may contain. The separate ledge theory holds each vein or ledge thus situated to be a distinct lode, no matter how many others there may be within the same mineralized zone.

NEVADA.

CHURCHILL COUNTY.

In the U. S. Circuit Court a judgment last week gives possession of the nickel properties in litigation to the Nevada Nickel Syndicate, an English corporation. The property was ordered sold to pay $28,504 and interest.

ESMERALDA COUNTY.

Hawthorne *Bulletin*: In the Huntoon valley, forty miles southeast of Hawthorne, F. M. and J. H. Lee have a ledge 2 to 8 feet in a depth of 30 feet. Water sufficient for a 10-stamp mill can be had within three miles of the mine, and wood is plentiful.

NYE COUNTY.

Bishop *Register*: Twenty-five miles east of Silver Peak the De Lamar Co. has bonded for $200,000 a property which gives assays of 276 ounces silver and $67 gold.

STOREY COUNTY.

Pumping at the C. and C. shaft on the Comstock continues without cessation. Manager Ross' latest telegram reads as follows:

VIRGINIA, Nev., Aug. 17, 1899.

To Aug. Waterman, Secretary Comstock Pumping Association, San Francisco—At 6:30 this morning the water was 20 feet 8 inches below the 1950-foot level station, the water having risen steadily during the past twenty-four hours, while the elevator was working continuously. A rush of water from some unknown source is probably the cause of the raise. We hope to start No. 2 elevator to-day. G. M'M. Ross.

The Sutro tunnel is being put in order and repaired from its mouth to the C. & C. shaft.

OREGON.

BAKER COUNTY.

The Banzette mine, Robinsonville district, was bought this week for $33,000 by Eastern, Spokane and local capitalists and the Banzette Con. G. M. Co. formed; incorporators, C J. Johns, Sumpter; B. Shipp, Baker City; J. M. Burke, Spokane; H. B. Branner, C. T. Gates, Knoxville, Tenn.; capitalization, 1,000,000 shares, par value $1 each. The new company will put up a pump and hoist, sink 200 feet on the ledge and build a 10-stamp mill.

LINN COUNTY.

Mining Review: A group of mines in the Bohemia district on Fairview mountain, belonging to Ziniker and Graber Bros., was sold recently to Eastern capitalists for $35,000. There are 1000 feet of tunnels and the ore is free milling. The vein is 3 to 5 feet wide. The new company will begin sinking a shaft.——Nelson & Edwards struck free gold while doing assessment work on their Peekaboo mining claim, a mile south of the Music mine, Bohemia. The vein is 3 feet 4 inches wide.

SOUTH DAKOTA.

CUSTER COUNTY.

Custer *Chronicle*: The Bismarck concentrating mill at Keystone is reported to be a success, and the company expects to erect another plant to treat the ore from the Big Hit mine. The concentrates from the Bismarck mill are being shipped.

UTAH.

BOX ELDER COUNTY.

Lewisohn Bros. will build a smelter at Copper mountain. E. Tuttle is Mgr.

JUAB COUNTY.

Nearly 200 men are now employed at the Mammoth mine.

At the Tetro of Tintic ore is reported that returns $90 in gold and twenty-five ounces silver per ton, and from a breast of quartz 6 feet in width samples obtained that gave 5 ounces in gold, with 21.8 ounces silver per ton. The quartz in which the values have appeared is 1500 feet from the mouth of the tunnel and is streaked with iron.——The new strike in the Star Consolidated at Tintic is developing. The drift on the 600 level, by which it was opened, has progressed 30 feet, the shoot being followed in opposite directions. In each of these laterals, ore is exposed in top, sides and bottom, the copper streak showing 12%. The drift off the 300-foot level has broken into ore again in a shoot independent of that at the 400.——In the Grand Central the main shaft has reached a depth of 800 feet and still sinking.

Manager John Hunt of the May Day has shipped a carload of fine ore to Salt Lake. With the completion of the electric power line of the Telluride Co. they will put in a hoist, when the output will be increased. The Telluride Power Co. has its pole line finished to Tintic and is stringing wire from the Provo end. Several properties are awaiting the completion of the line and will put in electric machinery.

Tintic *Miner*: The drift from the 300-level of the Showers Con. shaft at Diamond has cut the vein at 40 feet from the shaft and exposes 20 feet of ore, a large part of which is shipping grade. The ore is galena and lead carbonates, the silver values of which run 300 ounces.——At the Apex group, above the Uncle Sam and Godiva mines, a 25-foot body of quartz was cut by the tunnel recently that yielded good assays in lead, with silver.

SUMMIT COUNTY.

The Marsac mill and tailings dump are affording a source of revenue. Recently 20,290 pounds of silver sulphides were shipped, worth $200,000. This represents the output since the mill resumed the last time. In addition to this source of revenue are the crude ores.

It is reported that the Ontario tunnel has connected with the Daly workings. When the vein is reached it will be at a depth of 1700 feet—700 feet above the greatest depth of the old workings. J. Quinn, formerly foreman, is picking over old ore bodies under lease.

Park City *Record*: Parties working a portion of the West-Ontario on a lease and bond will drift for the vein. They are down 75 feet, and by running a drift 25 feet in a southerly direction, they expect to cut a vein of high-grade ore that they know is in the ground.

SALT LAKE COUNTY.

At Bingham in the Dalton & Lark a distinct and independent copper and gold-bearing shoot has been discovered. The shoot was opened by the drift south from the 640 level, where, after it passed through 2 feet of copper, it broke into galena. Assays from the copper ore show 12%, with some gold. In the drift running south on the 800 level a body of galena was found a few days ago.

Bingham *Bulletin*: In the Morning Star No. 1, while clearing out an old tunnel which has not been used for twenty years, a breast of shipping ore 5 feet wide was encountered recently and the output keeps two teams busy hauling.——Several fine specimens showing native copper have been taken from the main ore body in the Congor properties recently, and a large quantity of ore is now in sight. Shipping will begin soon.——The Dewey mill is again running on Neptune ore, under lease to Sampson & Sherman.

TOOLE COUNTY.

Salt Lake *Tribune*: Mgr. McVichie of the Golden Gate mine has increased the daily output to 1350 tons. The caving method of extraction is employed.

WASHINGTON.

(Special Correspondence).—The Black Bear and Crown Point mining claims are on Railroad creek, eighteen miles west from Lake Chelan, Okanogan county, in the Stehekin mining district. The property contains two veins, one 8 feet wide, composed of a white quartz carrying free gold and silver, assaying on the surface $8, and also molybdenite thickly embedded all through it, from the size of a hen's egg to that of a man's head. The dip of this vein is 45° and the walls are granite. An order has been placed by a New York firm for three carloads of it per month at $100 per ton f. o. b. at Wenatchee. A Philadelphia firm has offered $195 per ton for it if it runs 50% pure, and for every unit it runs over 50% will pay $2 50 extra. Average samples tested in New York and Montreal show this molybdenite to be practically pure. The other vein on this property, lying in granite and diorite, is a well-defined vein 3 feet wide with an 18-inch paystreak running gold $2.89, silver $1.18, copper 14.52%, total $57.79.

Lake Chelan, Aug. 10th, '99.

(Special Correspondence).—The Sunset Copper M. Co. reports substantial progress in the development of their copper property near Index. The holdings comprise thirteen claims, through four of which a ledge of bornite and chalcopyrite ore is traceable. Development consists of about 1200 feet of work on drifts, crosscuts, open cuts and raises. The width of the ledge is said to vary from 20 to 41 feet, within which is a pay streak as wide as 4 feet in places. A crosscut encounters the ledge in a distance of 230 feet, at which point the vein matter is 4 feet in width. Drifts are driven both ways on the vein. A tramway was recently built from the mine to the railroad station, six miles distant. It is stated that ore shipments will begin this month.

Index, Aug. 12th, '99.

OKANOGAN COUNTY.

(Special Correspondence).—The Methow district, east of Lake Chelan, is being developed slowly. The outcrop showing of that section is good, though the mountains are precipitous. The ores are iron and copper sulphides, with arsenides, the values being chiefly in gold and copper. Some of the ore will average $70 to $80 per ton gold and from 1% to 7% copper.

Among the properties being developed are the Orient, Marbie and Trinity. A contract to drive a 400-foot tunnel on the Marble has been let. W. Rust, of the Tacoma smelter, is interested in the Marble, which has a large body of ore.

The Oregonian, St. Lawrence and Big Eight, in the same locality, are preparing to develop.

Chelan, Aug. 13th, '99.

J. W. Heggarty of this county is reported as saying "there are no free-milling properties in the Okanogan country. They may show free-milling ore on the surface but not at depth. The values are there, but the ore is not free milling, and it's a mistake to hustle a stamp mill onto a mine without having attained sufficient depth to know what the character of the ore is. We are not building stamp mills in Okanogan. Concentrators are needed until railroads come, and then smelters at home."

Spokesman-Review: Reports from Myers Creek district, on the reservation, state that McEntire, McDonnell & Co. have cut a vein in the Review mine, 48 feet between walls. The crosscut is made on a large swell in the vein.

SNOHOMISH COUNTY.

Seattle *Post-Intelligencer*: The Ethel group of claims, 4¼ miles from Index, have been sold by Fourtner & Engle to G. A. Pounder of Seattle. The price, it is said, was $45,000. Mr. Pounder will put 20 men at work. He thinks that five of the mines will be shipping a carload of ore daily by January 1st.

STEVENS COUNTY.

The crosscut tunnel in the Golden Lion mine has reached the Mountain Lion vein, at a distance of 440 feet from its mouth.

WYOMING.

CARBON COUNTY.

The Eureka vein at Grand Encampment, at a depth of 20 feet, has widened from 2 feet to the full width of the shaft. The ore contains sulphides and oxides of copper.

FOREIGN.

BRITISH COLUMBIA.

A petition for the dissolution of the Le Roi Mining & Smelting Co. has been filed by a majority of the stockholders.

The Rossland Miners' Union have decided that hereafter no member of the union should be allowed to do contract work in the mines of that camp.

A rich find of coarse gold is reported on Horsefly creek, Cariboo, on the Ward Shaw property, and a "rush" is anticipated.

A press dispatch from Nelson says: Hennessey Brothers have bonded their claims on Sixteen Mile creek for $300,000 to Spokane parties. There is a 10-foot ledge of solid galena traversing the claims, and an iron cap 15 feet wide carrying fair values parallels it. Nothing but surface work has been done.

F. McCathy, Mayor of Revelstoke, and I. T. Brewster have returned with reports of a big gold strike seventy miles away, on Smith creek, in Big Bend district. A rush has commenced to the new mines. Both placer and quartz discoveries have been made.

British Columbia *Mining Record*: The Cariboo mine at Camp McKinney continues to make a good showing, the dividend last month swelling the total profits to $348,000, in all twenty-seven dividends. The success of the Cariboo mine is due to systematic development, good management and reasonable capitalization.

CHINA.

It is reported that the Russians have forced the Chinese officials in the Manchuria mining district to stop working the gold mines, which employ 2000 men, and will take possession of them. The Russians have also assumed possession of the coal mines north of Moukden.

MEXICO.

A. J. King will build new reduction works at the Cinco de Mayo mine, Pilares district, Sonora.

Two Republics: In Pachuca the Santa Gertrudis mill will be running in a few weeks.——Within a year a large pump will be put in the San Francisco mine. It will raise a stream 18 inches in diameter and has a capacity of 1500 gallons per minute.——At the San Guillermo a shaft of 530 meters is being sunk.——The San Rafael has declared a 10% dividend.——Early in September the smelter of the Trinidad M. & S. Co. will be in operation. The mines are fifteen miles from the Balsas.

SOUTH AFRICA.

Mining Journal: The Village Deep Co. will start crushing with 100 stamps, but it is intended that the eventual capacity shall be 800. It is a year and a quarter since work was started, and it will probably take from two and a half to three years before the necessary mine work has been completed to make a mill necessary. The Robinson Central Deep, which will put in 100 additional stamps to be erected at the Crown Deep mill, should strike the reefs about the middle of 1900. When the South Rand area has been adjusted to make a more suitable block, four and a half years may be allowed from the commencement of sinking to the milling stage, on a 100-stamp basis. At the Village Main Reef there is a likelihood of an increase to 200 stamps.

List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey, Strong & Co., Pioneer Patent Solicitors for Pacific Coast.

FOR WEEK ENDING AUGUST 8, 1899.

630,437.—FLUSHING TANK—C. J. Ball, Los Angeles, Cal.
630,438.—BUREAU—J. Barker, S. F.
630,649.—BICYCLE GRIP—F. A. Briggs, New Whatcom, Wash.
630,591.—SOLDERING MACHINE—W. S. Case, San Jose, Cal.
630,448.—ELECTRO-MAGNETIC ENGINE—M. S. Conly, Los Angeles, Cal.
630,488.—OILER—W. Cooper, Seattle, Wash.
630,495.—AIR COMPRESSOR—R. L. Dunn, S. F.
630,453.—CARRIER AND SERVER—E. W. Fairbanks, Los Angeles, Cal.
630,535.—BEET PULLER—I. Goble, Chino, Cal.
630,504.—MAIL POUCH FASTENER—W. E. Griffin, Reno, Nev.
630,830.—MECHANICAL MOVEMENT—S C. Houghton, S. F.
630,510.—ORE FURNACE—J. F. Keiper, Everett, Wash
630,511.—ROCK CRUSHER—J. H. Kinkead, Virginia, Nev.
630,512.—GEAR MECHANISM—A. Meyers, Spokane, Wash.
630,389.—CORSET FASTENER—Sarah R. Mills, S. F.
630,734.—BOWL HOLDER—Helena L. Oothout, Fresno, Cal.
31,379.—DESIGN—W. F. Clark, S. F.
31,343.—DESIGN—H. S. Winn, S. F.

NOTE.—Plain and Certified Copies of U. S. and Foreign patents obtained by Dewey, Strong&Co., by mail or telegraphic order. American and Foreign patents secured, and general patent business transacted with perfect security, at reasonable rates, and in the shortest possible time.

Industrial Notes.

—Montana woodchoppers are paid $1.40 per cord.

—There is a building boom in Salt Lake City, Utah.

—Skaguay expects to be the metropolis of Alaska. Juneau is.

—The Salt Lake Exchange has taken charge of Utah's mineral exhibit.

—An electric railway is projected by John Cross in Grass Valley, Cal.

—A new short railroad line is projected from Denver to Cripple Creek, Colo.

—Dillon, Montana, has voted $75,000 bonds to build a water works system.

—At Floriston, Cal., 100 men are employed on the site for the new paper mill.

—Returning soldiers from the Philippines say that country is not a good place for white people.

—The Canadian Parliament has voted $358,500 to be expended "for the encouragement of immigration."

—The electric and steam railway line between Seoul and Chemulpo, Korea, are in successful operation.

—A railroad from Stockton to Sacramento, Cal., is locally stated to be a present project of the Santa Fe Co.

—The Illinois Steel Co. announces its intention to give preference to English-speaking applicants for work.

—For the first time in the United States the "West" is loaning money to the "East," and investing in Eastern securities.

—The Kootenay Power & Light Co. have bought for $80,000 the property of the Rossland Water & Light Co., of Rossland, B. C.

—A big log raft, containing nearly 5,000,000 feet of timber, is being towed from the Columbia river 500 miles by ocean to San Francisco.

—The Oregon Short Line Ry. Co. has eight new chair cars costing $8500 each, three new buffet cars costing $9000 each, three new dining cars costing $10,700 each, and twenty-seven new locomotives.

—After the 1st prox. the republic of San Salvador announces a 50% reduction in tariff on steel in bars, sheets or plates, copper and brass in bars and sheets, plows, machetes and cutlasses to be used for work.

—The Southern Pacific Railroad will make a half rate for all exhibits or goods sent to the National Export Exposition, which opens in Philadelphia September 14th. Goods will be transported at the ordinary rates and returned free.

—The tunnel being bored through the Cascade mountains, Wash., by the Great Northern railway, is being worked from both sides and will be completed in 1901. It will be nearly 14,000 feet long, through solid granite, and needs no timbering.

—It is expected that next year through trains will be running between Port Arthur and Vladivostock and St. Petersburg. The first railway train to enter Manchuria rolled over rails from Philadelphia, nailed to ties from Oregon and hauled by an American engine.

—Japan's importations have grown in the past five years from 88,257,172 yen to 277,502,166 yen. (A yen is worth 49.8 cents gold in U. S. money.) Meantime her exports have grown from 89,712,864 yen in 1893 to 165,733,752 yen in 1898. The exports have doubled and the imports trebled during this period.

—Koshichi Tanabe & Co. is the name of a firm recently formed in Yokohama, Japan, with a capital of $75,000, to build an electric road in that city. About the end of September they will want bids on the various requirements from different manufacturers in England, Germany and the United States.

—The State Fair at Sacramento, Cal., from Sept. 4th to Sept. 16th inclusive, will be worthy of a visit from every miner who can find time to get there. Unusual interest is manifested in all the displays this year; about $40,000 premiums go in racing alone, and the exhibits in all departments will make the fair the most attractive one for years.

—The National Association of Gas and Gasoline Engine Manufacturers met at Detroit, Mich., on the 2nd inst for their first convention. The association was organized last April in Columbus, O., to regularly bring together manufacturers of gas and gasoline engines, to discuss matters of interest to them. The Detroit session was devoted to amending by-laws and putting the association on a regular footing. S. E. Baker of Springfield, O., was elected president; R. E. Weber, Kansas City, vice-president; A. S. Rodgers, Springfield, O., secretary and C. D. Dudgeus, Columbus, O., treasurer. The association will hold its next meeting in Chicago November 1st, '99.

—The Pennsylvania smelter at Sandy, Utah, will use electrical power throughout its entire plant. Current was turned on at the generating station in Big Cottonwood canyon last week, transmitted by aluminum wires six miles to the transformers and motors in the smelting works; a 40 H.P. motor operates an ore roaster, and a 50 H. P. motor an ore crusher. Motors capable of developing about 500 H. P. in all are installed at the smelter. There is transmitted a three-phase alternating current, through the medium of three No. 4 aluminum wires, at a pressure of 12,000 volts; at the smelter end of the line this high pressure is reduced by static transformers to 450 volts three-phase alternating current, then fed to the induction motors, which operate at 450 volts. Aluminum wire has about 60% of the conductivity of copper wire of equal cross-sectional area. The loss of pressure is eliminated by increasing the size of the wire.

Personal.

A. WARTENWEILER of California is in Butte, Montana.

O. O. HOWARD JR. is in Los Angeles, Cal., on mining business.

PAUL JOHNS is the new Supt. of the Crowned King M. Co. of Arizona.

CAPT. CASE succeeds H. Shipman as Supt. Cornucopia, Oregon, mines.

ALFRED PAGE, Wardner, is the Idaho agent for the Last Chance M. Co.

H. W. H. PENNIMAN has removed from San Andreas to Santa Cruz, Cal.

L. ALLEGEWAHR is again Supt. of the Thorpe mine, near San Andreas, Cal.

C. W. STICKNEY goes to Gunnison, Colo., as Supt. Granite Mountain G. M. Co.

L. C. CLARK, of Jno. Taylor & Co., San Francisco, has returned from Alaska.

M. MARCONI, of wireless telegraphy fame, expects to visit the U. S. next month.

D. B. HUNTLEY of De Lamar, Idaho, has returned from the Buffalo Hump country.

GEO. E. WOODBURY has returned to San Francisco from a business visit to Denver, Colo.

IRVING M. SCOTT, Mgr. Union Iron Works, San Francisco, has returned from Washington, D. C.

JOHN HAYS HAMMOND'S proposed visit to California is deferred by illness at Carlsbad, Germany.

F. M. JOHNSON, former Mgr. Tom Boy, Colorado, mine, is inspecting property at Bingham, Utah.

W. F. ARAM, mining attorney, has returned to San Francisco from a visit to Madera county, Cal.

JAS. JOHNSON is Gen. Mgr. and J. E. Clennel chemist at the new cyanide plant at Sonora, Mexico.

F. H. DAKIN, Supt. of the Uncle Sam mine, Shasta county, Cal., has returned to the mine from San Francisco.

EDWARD KERVIN, once in charge of a mine on the Comstock, Nevada, has a similar position in Ashanti, West Africa.

E. B. KIRBY of Denver, Colo., expects to return to that city in thirty days from a present visit in British Columbia.

J. W. NEILL, Supt. U. S. M. Co., Salt Lake City, Utah, is testifying in the Anaconda-Parrott suit at Butte, Montana.

JAS. QUINNE of Yreka, Cal., is in San Francisco to buy a 1000 H. P. dynamo for use in his Shasta river electric power enterprise.

RICHARD A. PARKER is now examining the zinc fields of southwestern Colorado and expects to return to San Francisco about Sept. 1.

BEN STANLEY REVETT has left Murray, Idaho, for Breckenridge, Colo.—interested there in dredging for gold—and from there goes to Oroville, Cal.

W. J. ADAMS of San Francisco, Cal., has gone to Mariposa Co., Cal., to make examinations of gold and copper mines. He will return in about a week.

VICTOR M. CLEMENT is in San Francisco, en route to the Spanish mine, El Dorado county, Cal., where quartz gold ore has been worked at a total cost for mining and milling of 62 cents per ton.

C. F. HOFFMAN, formerly Supt. of the Red Paint, Placer county, Cal., mine, who for three years has been in Siberia and the Argentine Republic for an English syndicate, is expected to return to California in August.

RECEIVER C. W. PAULY of the Golden Cross gold mines, Hedges, Cal., will be replaced by D. M. Delmas, I. Trumbo, J. Chandler, T. S. Fuller and D. T. Hedges, who will act as receivers without salary as long as the mine is in debt.

THE Union Pacific geological expedition now searching the fossil-bearing formations of Wyoming is headed by Prof. Wilbur C. Knight of the University of Wyoming, and not by Prof. A. R. Crook, as was stated in the issue of Aug. 5.

GEO. MCCULLOUGH has returned from Chemulpo, Korea, where he had charge of part of the extensive mining operations of J. Sloat Fassett. A 60-stamp mill is crushing $50 free milling ore. Native labor is 50 cents per day, and the capital invested in mining property there meets good returns.

THE jurisdiction and duties of the officials of the Florence & Cripple Creek R. R. Co. have been extended over the properties of the Golden Circle R. R. Co., the Canyon City and Cripple Creek R. R. Co., and the La Bella Mill, Water & Power Co. The officers of the Associated Companies are now as follows: Directors—S. T. Smith, E. Smith, G. E. Ross-Lewin, D. H. Moffat, W. E. Johnson. General officers—S. T. Smith, Pres.; E. Smith, Vice-Pres.; W. F. Jones, Sec'y, Auditor and Claim Agent; G. E. Ross-Lewin, Treas.; C. J. Hughes, Jr., Gen'l Counsel; T. S. Dines, Gen'l Attorney; C. F. Elliott, Executive Sec'y, Traffic Mgr. and Purchasing Agent; L. L. Summers, Consulting Engineer, all with headquarters in Equitable building, Denver, Colo. Officers of the lines—A. C. Ridgway, Gen'l Supt.; R. D. Stewart, Chief Engineer; R. Patterson, Master Mechanic; G. R. Simmons, Gen'l Storekeeper; C. S. Morse, Supt. Telegraph and Train Master; M. McGrath, Supervisor; M. J. Neligan, Road Master, all of the line officers with headquarters at Florence, Colo.

Catalogues Received.

BULLETIN No. 5134 of the Bullock Electrical Mfg. Co., Cincinnati, O., discusses construction details of the Bullock engine type generators, with half-tones thereof, diagram of efficiency curve, etc.

Notices of Recent Patents.

Among the patents recently obtained through Dewey, Strong & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

ROCK CRUSHER AND GRINDER.—Jas. H. Kinkead, Virginia City, Nev. No. 630,511. Dated Aug. 8, 1899. This invention relates to improvements for crushing and grinding rock. It consists of a grinding pan having a convex bottom with a flat circular central portion and inclined periphery extending upwardly and outwardly at approximately right angles with the conical portion of the bottom, an independent circular central die having a conical upper surface and outwardly and downwardly diverging periphery, a concaved bottom fitting the flat central surface of the pan bottom and extending a short distance down the inclined portion, a die having a central opening fitting over the periphery of the central die and locking it in place, said die extending to the inner periphery of the pan and having radial grooves or channels made at intervals around the periphery. In connection with this is employed independent removable segments resting upon the periphery of the die and forming a lining for the interior periphery of the pan; one or more split rings are fitted between the shoes and dies around this outer periphery and these take the wear as well as providing double grinding surfaces. Whenever these rings become worn too thin others may be inserted and the wear practically taken up.

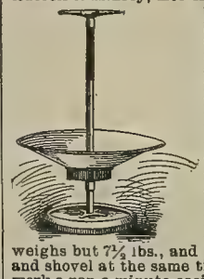
CAN SOLDERING APPARATUS.—W. J. Case, San Jose, Cal. No. 630,591. Dated Aug. 8, 1899. This invention relates to an apparatus by which square cans are delivered into holders and caused to traverse a solder bath with means for rotating the cans at stated intervals so as to present each of the edges to be soldered while the can is passing through the bath. It consists of a trough for melted solder, a framework fixed diagonally with relation to the trough having a support in which the sides of the cans rest and a second support against which the bottom of the can rests so that the angular edges will be submerged in the solder. A device is employed for moving and turning the cans consisting of an endless traveling chain, shafts journaled transversely of the chain and in line with the axis of the can, arms fixed to the upper ends of the shafts and fixed stationary lugs with which the arms engage successively as the chains travel, thus turning the shaft at intervals to submerge the new edge of the can in the solder bath. A transversely slotted disk is fixed to the lower end of each shaft and a carrier head is loosely attached to the disk and movable radially with relation to it. Arms project from this head and are adapted to clasp the end of the can so that the movements of the head will allow the angular can to turn as it moves through the bath.

MAIL POUCH FASTENER.—W. E. Griffin, Reno, Nev. No. 630,504. Dated Aug. 8, 1899. The object of this invention is to provide a reliable closure and fastening for the mouths of mail pouches. It consists of flexible hinged metal plates secured transversely across one side, and other plates across the flap which folds over the opposite side of the pouch, so that when the pouch has been closed and the flap folded over they form an absolutely rigid strip extending across both sides and the top of the pouch.

Recently Declared Mining Dividends.

The Missouri Zinc Fields Co., regular monthly dividend of ⅜ of 1% on preferred stock; Aug. 10.

The Aurora Zinc Co., regular monthly dividend of 17 cents per share on preferred shares; payable Aug. 25.



Morning Star Mining Co., Placer Co., Cal., $2 per share; Aug. 10.

Books Received.

"*Patents and How to Make Money Out of Them*," pp. 232, octavo, W. B. Hutchinson and J. A. E. Criswell; a practical work regarding patent procedure, official requirements, how best to introduce and make money out of an invention, etc. Published by D. Van Nostrand & Co., 23 Murray St., New York City; price, $1.25.

Alaska Gold Washer.

The Little Alaska gold washer, put out by Russell & Kinsey, Los Angeles, Cal., is built upon scientific and practical lines. The soil as thrown in is first brought to the center by the rotary motion, back and forth, then by a long whirl of the pan will be thrown out, while the gold of its own weight remains in the hollow cup at the center, from which it is impossible to dislodge it. This machine, costing only $6, weighs but 7¼ lbs., and one man can work it and shovel at the same time. Two men can work a pan a minute easily. Of course, it can use but very little water. They are being extensively used in this country, in Canada and Mexico. *

Commercial Paragraphs.

THE WOLFF & ZWICKER IRON WORKS, Portland, Or., have successfully launched the torpedo destroyer Goldsborough.

THE E. P. ALLIS Co. of Milwaukee, Wis., have leased the Lake Erie Engineering Works at Buffalo, N. Y., and expect to have 500 men at work there by September 1st.

THE MINE AND SMELTER SUPPLY Co., of Denver, Colo., has filed its articles of incorporation in Salt Lake City, Utah, where Mr. Warren C. Bogue has charge of the Salt Lake branch of the business.

THE Southwestern business of the New York Belting & Packing Co. is handled by the Los Angeles, Cal., Rubber Co. The New York Belting & Packing Co. has made what is claimed to be the largest piece of suction hose ever produced. Their line of hose for all purposes; of rubber belting under three different brands, of packing, gaskets and numberless specialties cover the whole range of needs in these lines, and the reputation of the company as pioneers and leaders in their line of manufacture always insures satisfaction to the users of these goods. The Los Angeles Rubber Co. also carries goods of the Carton Belting Co., full lines of rubber clothing of every description and druggists' rubber sundries.

THE results achieved by the Pioneer Mutual Mining & Exploration Co. of Los Angeles, Cal., will attract attention, as their plan is an adaptation of the building and loan idea to mine development. They propose to sell non-assessable stock, to be paid for in monthly installments, the income thus created being used for development work on an increasing series of likely properties. The dividends are to be derived from the profits of these properties, distributed among the stockholders on the basis of amount paid up on stock and time it has been carried. There is no treasury stock. Stock is non-assessable and non-forfeitable. The company is entirely mutual and may prove to be an available plan for developing minor properties of possible value.

THE city of Santa Ana, in Orange Co., Cal., has recently replaced two smaller boilers in the city water works with a 125 H. P. boiler, after their own specifications, made by the Gem City Co. of Dayton, O. It is built with double-butt straps, triple riveted and full flush front. In the same city, the packing plant of the Cutting Packing Co. has been completed. The steam plant comprises complete oil, water and feed pumps, heater, etc. Both outfits were furnished and placed by the Howe-Curry Co. of Los Angeles, Cal. This company, which has been recently incorporated, is the outgrowth of the business of Frank H. Howe, and carries a full line of milling and mining machinery, irrigating plants, engines, boilers, pumps, etc.

THE dredger built by the Bucyrus Co. of South Milwaukee, Wis., for Hingston & Woods, Buffalo, N. Y., for use on the Great Lakes, is said to be the largest dipper dredger ever constructed. The dipper has a capacity of 8¼ cubic yards (about twelve tons). The working capacity in water 25 feet deep is 5000 to 6000 cubic yards in ten hours. The hull of the dredger is of white oak and fir, 136 feet long, 42 feet 3 inches wide, 13 feet 6 inches deep, braced with four longitudinal steel trusses 119 feet long and 13 feet deep, two being placed at the sides, the other two spaced 26 feet apart, or 13 feet on each side of the center line. The sides of the hull are 8 inches thick, except at the bow, where the thickness is 12 inches; the bottom and sides are connected by 136 wrought iron knees. The hull and spuds contain 250,000 feet (B. M.) of timber. There are four spuds, the two at the bow each being 4x4 feet in section, made up of four 24x2¼-inch fir timbers 50 feet long; the two spuds at the stern are each 2x2 feet in size. Each bow spud is raised by means of a wire rope running over a sheave at the top of the spud. No attempt was made to distribute the weight of the hull so that it would float on an even keel, and when the spuds are off the bottom the bow sinks several feet lower than the stern. This arrangement was intended to place a preponderance of the weight of the hull at the forward end, to bear heavily upon the spuds and hold the dredger against the digging thrust of the dipper. The power applied to the spuds is able to lift the end of the hull 2 feet in the water, thus compelling the spuds to sustain a weight of about 180 tons. The A-frame and boom are of steel, the former 53 feet high, the latter 53 feet long, weighing thirty tons. The dipper handle is wood, reinforced with steel plates, and weighs sixteen tons. A noticeable feature of the dredger is the use of a single-part wire rope hoist for the dipper, instead of a chain hoist in several parts. The hoisting rope is of extra flexible plow steel, 2½-inch diameter, running over a sheave 8 feet in diameter, at the end of the boom, and another sheave of like diameter at the foot of the boom. The hoist is operated by an 18x24 inch double, high-pressure engine. The considerations which led to the adoption of a single-part cable for the hoist were the saving in weight and rapidity of action. It is estimated that a hoisting chain to do the work of this dredger would necessarily have to be in three parts, requiring a chain 2⅞ inches in diameter and 275 feet long, weighing about ten tons.

THE Cochrane feed water heater and purifier is having a great sale. Parke & Lacy Co., 21-23 Fremont St., San Francisco, are the sole Pacific coast agents. Among recent buyers of this money saver and economical appliance are: Bethlehem, Pa., Steel Co., 12,000 H. P.; Pennsylvania Mfg. Light & Power Co., Philadelphia, 3000 H. P.; Waterbury Rope Co., New York, 850 H. P.; Durham Iron Works, Reigelsville, Pa., 600 H. P.; Blodgett Estate, Boston, 300 H. P.; Thorley Bldg. (Pabst Brewing Co.), New York, 300 H. P.; E. P. Allis Co., Milwaukee, Wis., 200 H. P.; American Nut & Bolt Works, Cleveland, O., 350 H. P.; People's Independent Rice Mill Co., Crowley, La., 350 H. P.; Plaza Hotel, New York, 300 H. P.; International Paper Co., Franklin Falls, N. H., 350 H. P.; Providence Machine Co., Providence, R. I., 250 H. P.; Lorain, O., Street Railway Co., 850 H. P.; Warden Power Bldg., Philadelphia, 1000 H. P.; Pittsburg, Pa., Brewing Co., 600 H. P. Recent sales of Cochrane separators were as follows: Red Oak, Ia., Electric Co., 5-inch; Bellefonte, Pa., Furnace Co., 10-inch; U. S. Navy Yard, Bremerton, Wash., 4½-inch; Pressed Steel Car Co., McKees Rocks, Pa., two 3-inch, two 5-inch, three 6-inch, two 7-inch; Benj. Atha & Illingsworth Co., Newark, N. J., 7-inch; Edison Electrical Illuminating Co., Topeka, Kan., 6-inch; Howe-Browne & Co., Pittsburg, Pa., 10-inch; McCormick Harvesting Machine Co., one each 6-inch, 5-inch, 4-inch, 10-inch and 14-inch, and four 3½-inch; Norfolk Navy Yard, Portsmouth, Va., two 4-inch; East Jersey Water Works, Little Falls, N. J., two 8-inch; Waterbury Rope Co., New York, 6-inch; Armour Packing Co., Kansas City, Mo., 14-inch, 16-inch and 20-inch; G. A. Suter & Co., New York, 8-inch; Hecht Bldg., Boston, 5-inch; Illinois Steel Co., Joliet, Ill., 22-inch Vac. Oil; Pittsburg Valve & Machine Co., Latrobe, Pa., 3-inch; E. Keeler & Co., Williamsport, Pa., one 8-inch and two 6-inch; Euston & Co., Chicago, 5-inch; Cleghorn, Eglee Co., Boston, 5-inch; Columbus, O., Street Railway Co., 20-inch Vac. Oil; Ostby & Barton Co., Providence, R. I., 4-inch; Michigan Portland Cement Co., Quincy, Mich., 3½-inch and two 6-inch; P. Lorillard & Co., Jersey City, N. J., 6-inch; Salem Iron Co., Leetonia, O., two 12-inch, one each 6-inch and 3-inch; Wheeler & Wilson Mfg. Co., Bridgeport, Conn., three 1¼-inch and one 10-inch; Fabrica de Hielo, Manila, Philippines, 8-inch; Page Woven Wire Fence Co., Monessen, Pa., special 7-inch; Carbondale, Pa., Machine Co., two 1½-inch Ammonia and 3-inch; Chicago, Ill., Telephone Co., 8-inch; Torpedo Boat No. 34, Tingey, two 5¼-inch and one 1½-inch. The Parke & Lacy Co. are also sole Pacific coast agents for the Cochrane separator.

M. & E. Ore Cars.

The M. & E. ore cars have several strong points to recommend them. No part is made unnecessarily heavy and none so light as to be easily broken or quickly worn out. The box is made entirely of steel and swings easily to dump in any direction. The wheels are cast

iron and all other parts are of forged and hammered wrought iron or steel. The Mining & Electric Co. of Los Angeles, Cal., supply cars of all sizes in any weight required; standard gauge (18 in.) unless otherwise ordered. Estimates on special weights or sizes promptly furnished. The M. & E. Co. are finding only the highest praise for Cling-Surface belt dressing and state that not a single person who has used it according to directions has ever claimed that it would not produce all the results claimed for it. It is different from any other dressing in that it produces an absolutely clinging surface on any belt, whether leather, rubber, or a rope drive; it does not become sticky, it simply *clings*. The material fills the pores of the belt, making it as soft as calfskin and at the same time firm. When once well filled with Cling-Surface a belt pulls like a chain and can be run so slack that the sides almost touch, and all slipping is absolutely prevented. It is positively guaranteed to do these things and to permanently increase the power. *

The Homestake Mine.

At the Homestake mine, in Lead City, South Dakota, the Ellison hoist is about completed and all the machinery is rapidly being installed. Its capacity is 500 H. P. and will lift a double-deck cage from a depth of 3500 feet, loaded with four cars of ore containing one ton each. The hoist is located on the southern dip of the largest vein of gold producing ore in either hemisphere; it will ultimately be mined to a much greater depth.

The Homestake operations embrace 6000 feet in length by 2000 feet in width, and within this area, it can safely be said, that 5% of all the material composing the mass will yield down to the explored depth of 850 feet not less than $4 to the ton in gold. The associated companies composing the syndicate lift from the mine every twenty-four hours each day in the year and crush in their stamp mills about 3200 tons of ore, or in the aggregate for the year 1,168,000 tons of rock, from which is recovered $4.80 per ton, which gives an annual production of $5,496,400. According to Supt. T. J. Grier's report, the 3200 tons of ore which is mined and milled every day can be continued for twenty years from the ore already blocked out above the 800-foot level.

The Homestake mine was incorporated Nov. 5, 1877. The first mill of eighty stamps commenced crushing on July 12, 1878, and another of 120 stamps, the Golden Star, was added in 1879. The Homestake mine, since December, 1879, has paid dividends continuously, and up to this date has mined approximately 22,000,000 tons of ore, valued at more than $80,000,000.

The combined width of the gold-bearing veins, where the Ellison hoist is situated, is nearly 1000 feet, and widening as lower levels are exploited. It is stated that developments now expose sufficient ore to furnish mills of 5000 tons daily capacity for twenty-five years, a total of 45,625,000 tons. The dividends paid since the inauguration of mining on the belt is approaching the $12,000,000 mark, with the mine in a better condition to increase the net monthly profits than since the first mill was built.

The yearly labor and supply expense of the companies under the management of Mr. Grier is about $2,500,000, the number of men employed in all departments being about 2000. This concern leads in the economic mining of gold ore in the United States. The equipment for concentration is nearly perfect, and practically all the sulphides are now saved. This being accomplished, attention is being directed to cyaniding the quartz gangue, which contains the small amount of 70 cents to $1.25 per ton after the ore has been amalgamated and concentrated.—Deadwood Independent.

WIRELESS telegraphy will perhaps have its first great test during the holding of the National Export Exposition to be held in Philadelphia during the fall. No effort will be made to duplicate the Eiffel Tower, but a structure of some kind is being considered that will hold up a copper wire 1000 feet in air. It is claimed by Marconi, the inventor of wireless telegraphy, that if this is done by the Exposition people he will telegraph by flashes of electricity from the top of Eiffel Tower in Paris.

Antidotes for KCN Poisoning.

The increasing use of cyanide of potassium, and the number of cases of cyanide poisoning continually occurring in gold recovery works, makes it desirable for all engaged in cyanide works to be familiar with the best known antidotes. Sometimes the precipitate obtained by swallowing ten grains of ferrous sulphate, with one drachm of the tincture of ferric chloride in an ounce of water, and followed by a dose of twenty grains of potassium carbonate dissolved in an ounce of water, proves effective. Peroxide of hydrogen, sold by most druggists under the name of pyrozone, or aqua hydrogenii dioxide, is also favored. It is employed as a 3% solution for washing out the stomach, and for hypodermic injections which are made every four minutes in different parts of the body. Dr. Johann Antals' nitrate of cobalt remedy is also good. A. Wauchope, of the Woodside Cyanide Works, Woodside, South Australia, states that several years ago, when he was employed at the Australian Gold Recovery Co.'s Works, at Cobar, New South Wales, he experimented with this remedy. He obtained a rabbit and injected a solution of cyanide of potassium into its stomach. The effect of the poison was seen almost immediately, and in a few minutes the rabbit appeared to have breathed its last. When he could not detect any further action of the heart, he leisurely forced a solution of cobalt nitrate down the rabbit's throat, plunged it into cold water and breathed into its nostrils. After the lapse of one minute the muscles began to show signs of returning animation, and in the course of about ten minutes the animal attempted to run away. He caught it again, and to make sure that the cure was permanent, kept it until the following day, when it effected its well-earned liberty by hopping away as lively as a cricket. An excess of cobalt is necessary, and its effect is to form an insoluble flesh-colored precipitate, which, on account of its insolubility in the stomach, is evidently non-poisonous. Mr. Wauchope has such a high opinion of the nitrate of cobalt as a remedy in cases of cyanide poisoning that he has some always on hand at his works, and recommends his friends to keep it.—London Mining Journal.

A BRITISH COLUMBIA MINER has invented a hammer hand sling, which is intended to be an assistance to miners when drilling an overhead hole. The idea is to transfer the weight of the hammer from the handle grasped by the hand to the wrist or forearm by a sling connecting the head of the hammer and the wrist of the operator and a clutch connecting the handle of the hammer to the sling, so that the workman can sling the hammer and strike the drill without the effort of constantly grasping the hammer handle.

"GIANT" SHOES AND DIES.

Made of hammered steel, forged and hardened by special process. These shoes and dies are made in San Francisco and can be furnished within a week after receipt of order.

No. 1 Special Button Balance with 5-inch beam. Sensibility 1-200 Milligramme. Made for particularly accurate and rapid work and is guaranteed to be the finest balance on the market. It is the balance used by Prof. Forsythe of the Lawrence Scientific School, Harvard University, for scientific research. Send for Catalogue A, illustrating and describing a full line of assay and analytical balances, to

All of our latest improvements are embodied in this instrument and it is the result of our 18 years' experience in building balances.
Among the noteworthy features in the make-up of this balance is the improved adjusting device, herewith shown.

The adjusting device will appeal to the assayer as the simplest and most convenient means of checking the beam, and consists of a star wheel on a threaded arbor, mounted on the center edge back of the beam.
By turning this wheel backward or forward, it is moved along the arbor and so adjusts the beam to equilibrium.

General Arrangement of Pelatan-Clerici Plant.

The "Pelatan-Clerici" Process

OF TREATING REFRACTORY ORES

Saves the precious metals by the simplest, most economical and most efficient process known. No roasting or previous treatment, except ordinary crushing. Extraction complete in from 6 to 12 hours. Extracts equally well both fine refractory gold and coarse gold in the form of amalgam. Makes a greater saving of gold than any other process from raw material at less cost. The electric current and dissolving agent promptly dissolve the precious metals, both gold and silver. Samples of ore tested free of charge. Several mills saving over 90 per cent of values by bullion returns. Simplicity. Economy. Efficiency.

Market Reports.

SAN FRANCISCO, Aug. 17, 1899.

SILVER.—London, 27¾d; New York, 60¼; San Francisco, 60¼; Mexican Dollars, 49@50; New York exchange, sight, 10; telegraphic, 12½ cents premium.

LEAD.—New York reports quiet, $4.57½ bid, $4.62½ asked; brokers' price, $4.35.

Local, pipe, 7¼@7¾c; sheet, 7¼@8¼c; pig, 6¾c; bar, 6¾c.

COPPER.—New York reports Lake unchanged at $18.50; brokers' price, $18.75. Local—Mill copper plates, 23½c.

The copper market remains practically unchanged. The demand continues unabated and the supply does not change materially.

IRON.—American, soft, $22.50@24.50 per ton; Scotch, $27.50 Local bar, 2¾c per lb.

Iron is firm. The mines are making great effort to make as large an output as possible, but it is absorbed as fast as it appears, and higher prices may be looked for until some new source of cheap ore is discovered. Vigorous prospecting is in progress.

STEEL.—11¼@20c per pound.

TIN.—Dull; $31@31.25; pig, 36@39c per lb.

There appears to be an increasing demand for tin with a decreasing output. The visible supply is small. The fluctuations in price are the result of brokers' operations.

ANTIMONY.—In San Francisco 1000 pounds and upwards, 10c net; 300 to 500 pounds, 11@14c; less than 100 pounds, 15c.

BABBITT METAL.—No. 3, 8¾c.

QUICKSILVER.—Local, $43.50; export, $39.50@40; carload lots, special rates.

PLATINUM.—London, 63⅛s per ounce; York, $16.25; San Francisco, $16.75.

ASSAY LITHARGE.—100 lbs., 12c.

MINE PROMOTERS AND BROKERS.

Make a specialty of promoting, operating and developing mines. We handle all standard stocks.

Our specialties are: Syndicate G. M. Co., Syndicate Camp, Idaho; Admiral Dewey G. M. Co., Republic, Wash.; Mabel G. M. Co., Republic, Wash.; Juno M. & M. Co., Republic, Wash.; Ninety-Eight G. M. Co, Republic, Wash. Send for free maps of Republic Camp. Codes used: Moring & Neal and Clough's.

A Fortune Maker.

The oil fields of California are rivaling those of the world as fortune makers for the lucky investors. Stocks that are now selling for a few dollars will bring hundreds and in some instances thousands per share

When Oil Is Struck.

We have 2000 acres right in the wonderful Panoche Belt. The leading experts declare it positively oil bearing. Sinking of wells commences immediately. Our stock is $4 per share now. A few shares may fix you comfortably for life. Prospectus with full particulars free.

Salmon River & Liberty Mining District. Price reasonable. Address owner, H. H. MERRIAM, P. O. Box 93, Sawyers Bar, Siskiyou Co., Cal.

..CRIPPLE : CREEK..

FOR SALE—CYANIDE PLANT,

100 tons daily capacity; in first-class condition to handle Cripple Creek ores.

Plant in full running order, with all latest improvements. Address JOHN S. MACBETH, Equitable Building, Denver, Colorado.

THE CALIFORNIA DEBRIS COMMISSION, having received applications to mine by the hydraulic process from J. S. Goodwin, in the Birdseye Creek Placer Mine, at You Bet, Nevada Co., to deposit tailings in an old pit; from Mrs. E. A. Cox, in the Washington Mine, at Whiskey Diggings, Sierra Co., to deposit tailings in Fourth Ravine; and from Geo. W. Stone and Jas. J. Schenrich, in the Red Hill Gravel Mine, near Diamond Springs, El Dorado Co., to deposit tailings in a ravine and in Ringgold Creek, gives notice that a meeting will be held at Room 59, Flood Building, San Francisco, Cal., on September 4, 1899, at 1:30 P. M.

An Oil Proposition IN Southern California.

A guaranteed product of 5000 barrels per month, with two additional wells almost ready to begin pumping, which will without doubt increase the output to 6000 barrels monthly. Fully equipped with two good pumping plants—boilers, engines, derricks, tanks, etc., etc., with ample territory and a prompt sale for all oil at the wells at a good price. We offer this property for a short time at a price that will enable the product to pay for it within a year. For particulars, address THE O'BRIEN INVESTMENT CO., No. 218 So. Broadway, Los Angeles, Cal.

Assessment Notices.

SAILOR CONSOLIDATED MINING COMPANY.—Location of principal place of business, San Francisco, California; location of works, Placer County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 12th day of July, 1899, an assessment (No. 1) of eleven cents (11c) per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the secretary, at the office of the company, 318 Front street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 21st day of August, 1899, will be delinquent and advertised for sale at public auction, and, unless payment is made before, will be sold on MONDAY, the 18th day of September, 1899, to pay the delinquent assessment, together with the costs of advertising and expenses of sale.

By order of the Board of Directors.

M. C. LUND, Secretary.

Office—318 Front street, San Francisco, California.

MARGUERITE GOLD MINING AND MILLING Company.—Location of principal place of business, San Francisco, California; location of works, Auburn, Placer County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 19th day of July, 1899, an assessment (No. 14) of 10 cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the secretary, at the office of the company, 237 12th street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 28th day of August, 1899, will be delinquent and advertised for sale at public auction; and unless payment is made before, will be sold on MONDAY, the 25th day of September, 1899, to pay the delinquent assessment, together with the costs of advertising and expenses of sale.

By order of the Board of Directors.

F. METTMANN, Secretary.

Office—237 12th street, San Francisco, California. The Secretary will also receive payments from 12 to 5 P. M. at his business office, 225 Sansome street.

CENTRAL EUREKA MINING COMPANY.—Location of principal place of business, San Francisco, California; location of works, Sutter Creek, Amador County, California.

Notice is hereby given that at a meeting of the Board of Directors, held on the 25th day of July, 1899, an assessment (No. 13) of three cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin to the secretary, at the office of the company, room 9, 320 Sansome street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 1st day of September, 1899, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on MONDAY, the 25th day of September, 1899, to pay the delinquent assessment, together with the costs of advertising and expenses of sale.

By order of the Board of Directors.

WM. A. M. VAN BOKKELEN, Secretary.

Office—Room 9, 320 Sansome street, San Francisco, California.

MARIPOSA COMMERCIAL AND MINING COMPANY.—Location of principal place of business, San Francisco, California; location of works, Mariposa County, California.

Notice is hereby given that, at a meeting of the Board of Directors, held on the 28th day of July, 1899, an assessment (No. 12) of ten ($10) dollars per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the secretary, at the office of the company, 320 Sansome street, room 24, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 5th day of September, 1899, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on FRIDAY, the 29th day of September, 1899, to pay the delinquent assessment, together with the costs of advertising and expenses of sale.

By order of the Board of Directors.

JOSEPH H. MOOSER, Secretary.

Office—320 Sansome street, room 24, San Francisco, California.

EUREKA CONSOLIDATED DRIFT MINING COMPANY.—Location of principal place of business, San Francisco, California; location of works, Forest Hill Divide, Placer County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 10th day of August, 1899, an assessment (No. 20) of one-half cent per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the secretary, at the office of the company, No. 1209 Claus Spreckels building, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 12th day of September, 1899, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on SATURDAY, the 30th day of September, 1899, to pay the delinquent assessment, together with the costs of advertising and expenses of sale.

By order of the Board of Directors.

J. J. CRAWFORD, Secretary.

Office—1209-11 Claus Spreckels building, San Francisco, California.

NO MORE PACKING DIRT TO WATER.

——THE——

PNEUMATIC PROSPECTOR.

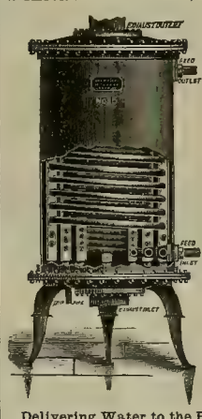
Size 6x11x14 in. Weight only 10 lbs.

PACKED FOR MOVING.

NO WATER NEEDED.

Gives a clean prospect from placer ground or free-milling ore by compressed air. The operation is purely mechanical. No chemicals, no quicksilver; no black sand remains with the gold. Will do work equal to careful panning.

THE PNEUMATIC SEPARATOR.



Weight 160 lbs.

Has a capacity of 20 to 30 cu. yds. of gravel per day. Will save fine and coarse gold and nuggets of any size, comparatively free from black sand. Will do better work under favorable circumstances than a sluice box. Indispensable for dry countries.

Inventors on the Pacific Coast will find it greatly to their advantage to consult this old experienced first-class agency. We have able and trustworthy associates and agents in Washington and the capital cities of the principal nations of the world. In connection with our scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of patents already granted, for the purpose of determining the patentability of inventions brought before us, enables us to give advice which will save inventors the expense of applying for patents upon inventions which are not new. Circulars and advice sent free on receipt of postage. Address **DEWEY, STRONG & CO., Patent Agents, 330 Market St., San Francisco, Cal.**

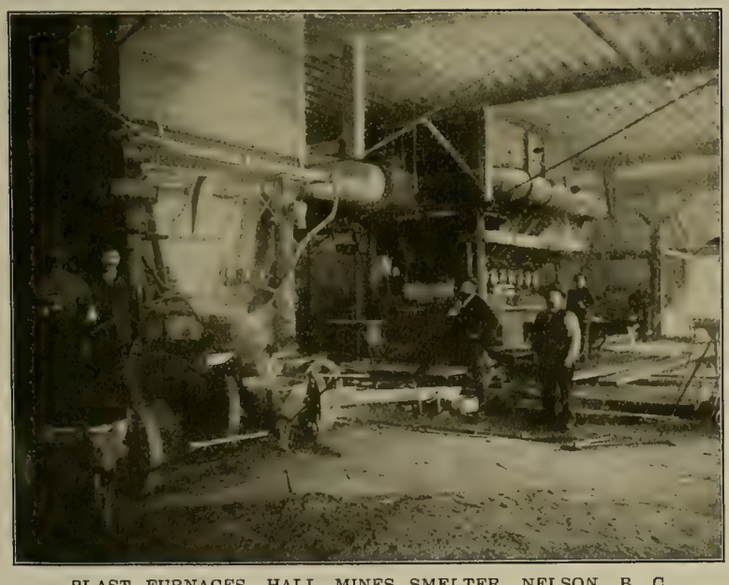
No. 2042.—VOLUME LXXIX. Number 9. SAN FRANCISCO, SATURDAY, AUGUST 26, 1899. THREE DOLLARS PER ANNUM. Single Copies, Ten Cents.

The Doratha Morton Mine.

The first cyanide plant installed in British Columbia is on Phillips Arm, 120 miles up the coast from Vancouver, in connection with the Doratha Morton mine, and is bonded to the Fairfax Exploration Syndicate of London, of which Mr. J. J. Lang of Vancouver is manager. An illustration on this page gives an outside view of the mill and leaching vats on the shores of Fanny bay, a branch of Phillips Arm. The mine is worked through crosscut tunnels and ore conveyed to the mill by wire tramway, where the ore is dumped onto a grizzly, the fines going to the bins and the coarse to the rock breaker and thence to the bins. The ore is crushed by stamps, from which it passes to the settling tanks (three in number) 20 feet in diameter and 7½ feet high. These tanks are provided with bottom discharge doors through which the ore is discharged into cars and conveyed to any of the treatment tanks (six in number) in which the ore is leached from six to eight days. The solution tanks are 20 feet in diameter and 10 feet deep.

The Van Anda mine is on Texada island, northwest of Vancouver. The ore bodies occur, according to the provincial mineralogist, in a limestone formation intersected by numerous felsitic dykes, the ore being intimately associated with the eruptives. The new shaft is down 230 feet. The view shown was taken at the 175 foot level. The shaft is in ore from top to bottom. The ore occurs scattered through the rock in irregular masses of bornite and chalcopyrite, carrying silver and gold. Much of it can be hand sorted for shipment.



Two of the illustrations on this page are of interior views of the Hall Mines smelter at Nelson, B. C., and convey an idea of the appearance of a portion of a reduction plant and something of the character of the labor. The smelter is on the hillside back of Nelson, and was built to treat ores from the mines owned by that company. Ores of the Silver King, one of the group, proved remarkably regular in composition. Mr. Robt R Hedley, superintendent, has stated to the representative of the Minister of Mines that the ores averaged throughout several years 37% silica, 8% lime, 6% magnesia, 10% ferrous oxide, 10% manganese oxide, 3% copper and 3 3% sulphur. No preliminary roasting was necessary, owing to the self-fluxing properties of the ore. The first furnace had dimensions at the tuyeres of 40x100 inches, giving a capacity of 150 tons of charge daily. In '97 a larger furnace was built, in which the dimensions were 44x144 inches, giving a daily capacity of 280 to 300 tons. More recently a reverberatory plant has been built, and the practice is now to calcine about one-half of the matte produced, and charge to the reverberatory about 8000 pounds of raw with 8000 pounds of calcined matte, and 1200 to 1500 pounds of quartz or silicious material, which in twelve hours will form a good bed of white metal.

Patents for Pacific Coast Inventors; Notices of Recent Patents; Recently Declared Mining Dividends; Obituary, 236. The Gigantic Fossils of Wyoming, 237.

IN the Missouri zinc fields the mine operators have formed an association for their mutual benefit. As a result, they have fixed a price on their product, which will be maintained for six months at least, and the smelters are buying, without protest, all that is being produced, at the miners' price. As another result of the co-operation of the miners, all night shifts have been discontinued for the time being, in order to regulate the output.

MINERS and prospectors should not allow themselves to be fooled by false newspaper "boom" stories and the ridiculous lies told by the transportation companies. On page 235 appears the truth concerning the Atlin district, written by an experienced miner and prospector. The statements of such a man, who knows what he is talking about and has no axe to grind, are to be believed rather than the extravagant assertions of those whose interests lie in luring away men with money to pay their expenses.

FROM necessity the prospector must be venturesome. Some of the richest mines known offered no great inducements on the surface, and some none at all, other than that there was a bare possibility that ore might be found by tunnelling or sinking. Capital seldom is willing to do much exploratory work without some previous showing, either upon the property they would explore or on adjoining territory. Capital is timid, sometimes too much so, but at other times it becomes too venturesome for the good of legitimate mining. Disaster to large capital in mining always has a reactionary effect. Many mines, abandoned by the original locators, are taken up by others, and in some instances there are several successive abandonments and relocations before the property shows value when it may eventually become a great mine. Such is the history of one of the most prominent mines of Butte, Montana. When a prospector does make a strike he usually either asks a price so great that he cannot dispose of his mine to a bona fide purchaser, or he sells at a price far below what it is really worth. The latter instance, however, is rare. The discoverers of one of Utah's greatest mines sold out for a moderate fortune and were secretly glad of the opportunity, admitting that they feared the deposit would not go down. The mine returned several millions in dividends to its purchasers.

Requisites of Mine Management.

The most essential requisite in a mine manager, aside from his ability to attend to the duties of today, is to anticipate the requirements of to-morrow and be prepared to meet them. To be successful the manager must understand his mine and have sufficient experience to foresee the necessities of the future. It is true that sometimes a man who, under more favorable circumstances, would perhaps prove a good manager is handicapped for lack of necessary funds to do that which he knows should be done. Timber is required, not only for the present season but for next season; transportation facilities must be improved, and everything must be done which will tend to reduce the expense of operation, even though at seemingly great cost for the present. When a successful mine manager called upon the directors of his company for a hoisting and pumping plant they inquired the cost. He said it should not be less than $80,000. After considerable discussion they wisely told him to put in whatever machinery he considered necessary, regardless of cost, but were somewhat surprised when the expense of the new installation was found to be $175,000. They thought it an unwarranted liberty, but were discreet enough not to say so. This plant has been in successful operation for years, and long ago demonstrated the wisdom of the superintendent who foresaw the need of it. A new and much larger plant is being installed at the same mine, at much greater cost, and nothing thought of it. The same manager built a railroad at great expense, but it paid for itself within five years. The mine manager is a busy man, but he must find time to read, for unless he does so his world is limited to what is going on about him—the creations of his own mind. He must also know what others in the same business are doing elsewhere, or he will soon be behind in the steadily onward march of the great industry. At no time were more rapid strides being made than now, and never before has there been so decided a tendency to break away from traditional methods and ideas; consequently the mine manager must read his technical paper and keep up with the progress of the day. He cannot afford to give too much attention to the small details of his business, but must exercise over all a general supervision. One of the distinguishing characteristics of a good manager is the care and judgment with which he selects men who are placed in charge of each department. The whole army of men is operated with almost military precision. He has a superintendent for each mine who is responsible to the manager; foremen who are responsible to the superintendent, and shift bosses who look to the foremen for instructions. In the mills or furnaces the same arrangement is to be found. Each man has duties to perform and he attends to them. It is the duty of the laborers to do the rough work, and that of the foremen or superintendents to give direction. When the $5 mechanic is seen packing lumber and the $2 man frequently fills his pipe, things about that mine are not well managed and there should be a change somewhere, and the general manager is the one who is responsible.

Another "Discovery."

August rarely passes without something that at least contributes to the gayety if not the lasting advantage of the mining world. The extraction of gold from sea water, the transmutation of silver into gold, and other pleasant pipe dreams of modern alchemists, this time receive the regular August contribution in the shape of a "discovery" by Mr. Theo. Olan, of Washington, D. C. Mr. Olan's "discovery" consists in finding "a new element which will soften steel, gold, silver and many other metals, making them soft, pliable and ductile as putty and as easily and safely handled." He has named the new chemical agent tauric acid, because it is obtained from tauric moss, a lichen, or fungus, which grows upon rocks and the roots of trees generally.

Mr. Olan puts "in a deep vessel a layer of chloride of lime, then a layer of tauric moss, to a depth of two inches, and then a layer of chloride of potash of about the same thickness. This is saturated with water until the lime is slacked away. After the fire has gone out of the lime the liquid is drawn off. After this, creosote of tar is added until a saturate solution results. The solution is precipitated with a solution of sulphuric acid, one part in ten. After precipitation the supernatent liquid is decanted, and the residue is found to consist of pure tauric acid."

The delight with which this knowledge will be received by metallurgists and metal workers is unhappily modified by the further statement that his new emollient "will not soften iron." This is indeed sad. But so long as steel, gold, etc., may now be "safely handled" by the aid of Mr. Olan's great discovery, the continued incorrigibility of iron in refusing to be similarly influenced can be borne with resignation.

The Causes of Mine Accidents.

Accidents in mines resulting in death have become so numerous of late that the inquiry whether something cannot be done to lessen these casualties is natural. In most cases it would appear that the trouble is in a great measure due to the carelessness of the injured men, though the safeguards in mines are not numerous. By daily familiarity with the workings miners become careless and subject themselves to danger where a strange miner or one wholly unfamiliar with mine workings would sustain no injury. Miners boldly work under ground known to be dangerous; they walk about on wet timbers far above the sill floor without the least concern, where any other person would cling timidly to a post for support; and in many other ways miners take what appear to the uninitiated to be desperate chances. Some of these elements of danger cannot easily be eliminated from the business of mining but others may to a great extent be guarded against. The injury which comes to men through carelessness in passing up or down a shaft on skips or cages may be avoided by employing enclosed cages for the men. Guard rails may be placed around shafts at stations; strict rules can be enforced concerning the keeping and handling of powder under ground, and various other provisions made to lessen the danger to men, but there is no way to wholly avoid the danger attending the catching up of a bad piece of ground, though it may be reduced to a minimum by taking the necessary precautions. Danger from blasting in the bottom of shafts may be avoided by the employment of the electric apparatus, but some mines do not even provide a ladder for the escape of men, depending solely upon the hoisting engine to raise them quickly from danger. While many of the accidents are due to neglect and parsimonious management, the greater number are due to the personal unconcern of the miners themselves, who when recognizing danger take no steps to have the condition bettered.

WITHIN a week two mining towns—Victor, Colo., and Placerville, Idaho—have been partially destroyed by fire, a fate which has fallen to the lot of almost every mining town of consequence in the Western United States. Leadville, Colo., is a notable exception. The highly inflammable material of which mining towns are usually constructed—pitch pine—is largely the cause of the destructive character of these numerous conflagrations. In a number of instances this, together with insufficient fire protection, has resulted in the complete destruction of a number of mining towns. Another element of extreme danger is the large amount of explosives kept within the town limits by dealers, as a matter of convenience. It has not infrequently occurred that it has been impossible to remove this powder to a place of safety, and the explosion which naturally followed has sent firebrands all over the burning town, rendering futile further effort to save what might have otherwise been spared.

COLORADO is once more mounting the wave of prosperity. After an idleness of several weeks, the smelters are again in blast, and the railroads are making strenuous efforts to relieve the congested condition of ore bins, dumps and loading platforms at mines and stations. Although the shut-down occurred at a most inopportune time, after an unusually long, severe and expensive winter, the mining men of that State hope to show by the end of the year no material falling off of the annual output. The smelter men wisely concluded to accept the offers made by the smelter owners, and all is now running smoothly.

Concentrates.

IN some districts galena is found in limestone which has not perceptibly altered.

MOLYBDENITE is not used on the Pacific coast. Concentrated, it is worth about $200 per ton.

A THIRD mining exchange is to be opened Sept. 1st at Colorado Springs, Colo., with reduced rates of commission.

A POWER OF ATTORNEY is an instrument authorizing a person to act as agent or attorney of the person granting it.

NO ONE method of mining iron ores is practiced in the United States. The conditions obtaining—character of the ore and form of deposit, etc.—usually determine the method of mining.

A PLACER CLAIM, the same as a quartz claim, may be patented in the same manner as a lode claim. Five hundred dollars worth of work must first be done, and then application for patent may be made at the United States Land Office for the district in which the mine is located.

VOLUME XXVI of the transactions of the American Institute of Mining Engineers, page 599, contains a comprehensive paper on the concentration of ores in the Butte district of Montana, by C. W. Goodale. A discussion of the foregoing paper appears in the same volume, page 1108.

THE law provides that the lateral extent of locations of veins or lodes shall not exceed 300 feet on each side of the middle of the vein at the surface, and no such surface right shall be limited by any mining regulation to less than 25 feet on each side of the middle of the vein at the surface.

THE highest price reached by quicksilver in the United States since 1850 was $118.55 per flask in '74–'75, and the lowest in '79, when it was $25.25 per flask. The largest amount ever output by any one mine in America was that of New Almaden, Cal., in '65, when the production reached 47,194 flasks.

IN the year 1883 but 83 pounds of aluminum were produced in the United States. In '84 the amount was 150 pounds and in '85 was 283 pounds. In '86 it was 3000 pounds. During the succeeding years the production increased rapidly. In '91 it had reached 150,000 pounds, in '95 it was 920,000 pounds, in '97 4,000,000 pounds, and 5,200,000 pounds in '98.

A FAULT in rock formations is a displacement which has taken place along a fracture. The movement ranges from a fraction of an inch to more than 20,000 feet. In many mining regions the faults play an important part in the economy of mining. This is particularly exemplified at Leadville and Aspen, Colo , where faults are numerous and often puzzling at first.

BEFORE driving a lengthy crosscut tunnel to exploit an ore body presumed to exist by reason of finding ore in shallow workings, it should be determined whether the ore will justify such expenditure. It may be that the ore does not go down, or, if it does, may not continue to carry sufficient value to warrant extraordinary expense. Such things are not without precedent. Better follow your ore.

SILVER occurs in ores native, as chloride or bromide, or more frequently in combination with other substances, as sulphur, arsenic, antimony, etc. Ores of this latter class usually require roasting before treatment. Chloride and bromo-chloride ores can be leached by solutions of hyposulphite of soda. Base ores may be subjected to chloridizing roasting, when the hyposulphite solutions may be successfully applied.

THE volumetric assay of copper ore is based upon the fact that, when dissolved in nitric acid, copper or any of its ores produces a clear green solution, which, upon the addition of an excess of ammonia, becomes blue; and upon the further fact that a solution of cyanide of potassium will discolor the blue solution of copper. The quantity of a standard cyanide solution required to effect this discoloration determines the percentage of copper.

MINING in Spain is heavily burdened. There is an annual royalty of 15 pesetas on minerals, a duty of 3% on the gross values of all ores extracted, an exportation tax, so much per ton on all ore shipped from Spanish ports, port dues, duty on explosives used in mines, an industrial tax on all mining apparatus, a stamp duty on each page of the required set of books used by mining companies, a 12% duty on the profits of railway transportation of ore, etc.

NO PLACER CLAIM made by a single individual can exceed twenty acres, and no local mining regulations can restrict a claim to less than twenty acres, though this is frequently done in new mining camps. A locator is not compelled to take as much as twenty acres, but may take that much regardless of local laws and agreements. It is presumed that local laws may determine the length which each claim shall have along the gulch or canyon; but where claims are short—300 feet—and the gulch narrow, the claims would necessarily extend high up on the hillsides.

TRAVELING REPRESENTATIVES of mining machinery houses traverse every part of the great mining region from Alaska to Central America. It is their universal testimony that wherever they go they find the MINING AND SCIENTIFIC PRESS. One of these gentleman writes that, when starting "on the road" some years ago, he regretfully discontinued his subscription, as from constant travel he feared he would be unable to get the paper with any degree of regularity, but finds it so universally taken in every place he visits that he is always able to read it every week as usual.

COMMERCIAL COPPER, as used for other than electrical purposes, is rarely pure. The effects of some of the common impurities, such as arsenic, nickel and silver, are supposed not to be detrimental; antimony is objectionable, and bismuth, even in small traces, prejudicial. The usual workshop test for the quality of copper is to cut off a portion of the pipe or sheet and anneal it, when it should stand bending close, without a sign of cracking. The edges also should stand thinning to a knife-edge without crack when hammered to a scarf-joint form with a lap of about three or four times the thickness of the copper.

THE principal ore of mercury is cinnabar (a sulphide); metacinnabarite also occurs, but more rarely. Mercury is employed in the manufacture of vermillion, which is either the natural or artificial sulphide in pulverulent form; in medicines, and the arts, but is principally used in the treatment of gold and silver ores in the process known as amalgamation. The greatest mines of cinnabar occur in sandstone, usually associated with serpentine. Its occurrence has been noted, however, in eruptive rocks in various places. These occurrences are not of commercial importance.

IT is usual in good practice to have wheels on lines of shafting close to brackets, to prevent the shafts springing and permitting a chattering action on the teeth. Such chattering induces breakage. The brackets should, if possible, be cast in one piece. The stress caused by the thrust of the wheels is thus resisted by the bracket. Trouble is otherwise apt to be caused by the brackets loosening on the foundations. This is especially the case if the wheels are slightly irregular through the distortion of a pattern or from some other cause. For the same reason brackets at the back of a pair of bevel wheels are bolted together or cast in one piece. They are then termed angle brackets.

A FAULT sometimes dislocates a vein in such a manner as to be very confusing to the prospector. If the fault occurs nearly at right angles to the course of the strike of the vein, and the "throw" is not too great, the prospector can readily understand what has taken place and knows how to proceed. Sometimes a fault occurs which nearly coincides with both dip and strike of the vein. The displacement may then result in doubling the vein, giving it twice its normal width, but a short distance away one side of it may be wholly lost, and the other side will flatten out and the vein present every appearance of playing out. By sinking and crosscutting one side may usually be found.

THE following is a suggestion for mounting plans on linen: Get a board or table sufficiently large to take the plan and tack the linen down with small tacks, of course minding that no creases occur in the linen. Get some common flour, to which add the proper proportion of water, and boil until the required thickness is obtained; with a smooth paint brush smear the linen evenly with the paste, taking care to leave no lumps on the surface; lay the plan to be mounted carefully on the linen, and with a handkerchief or soft cloth press the plan, making it tightly adhere. After this put the board aside for two days to dry, when the plan will be ready for trimming off with a sharp penknife.

ANTIMONY usually occurs as stibnite or sulphide of antimony, but is also occasionally found in the native state. Among its various compounds are berthierite (antimony, iron and sulphur) wolfsbergite (antimony, copper and sulphur), bleinierite (antimony, lead and sulphur). It also occurs associated with silver and sulphur and as antimonial (ruby) silver and as antimonial nickel. It is used chiefly as an alloy with other metals, and to a large extent with lead as type metal. It possesses the peculiarity of expanding at the moment of solidifying. Alloyed with aluminum it gives hardness and elasticity to that metal. It is injurious to copper, as a single part in 1000 destroys the good qualities of that metal.

WHERE narrow mortars in stamp mills show signs of wear, they may sometimes be lined with steel plates by resetting the stamps. Ordinarily stamps are set at 10 inches between centers, the stamp heads and shoes being 8½ inches in diameter. The space between the stamps is 1½ inches. This may be reduced by substituting a new set of guides, reducing the distance to 1 inch or even to ¾-inch, thus gaining from 1 to 1¼ inches at each end of the mortar—sufficient room for the insertion of substantial lining plates, which, by being replaced, will give a much longer life to the mortar. Mortars cast with the intention of being supplied with liners are somewhat longer and come fitted with liners on all sides when new.

WHEN one or more persons have made a location of 20, 40, 60 or more acres of placer land, in a single tract, they may elsewhere locate additional claims. The location of a placer claim requires a bona fide discovery, the same as a quartz location. If a location be made without such discovery it is not a valid location, and a second party later making a discovery can legally claim the land, and hold the same against the first locator. Placer locations may be made in subdivisions of ten acres each where land has been previously surveyed by the Government, and the locations must conform as nearly as possible to the surveyed lines of the land. It is not absolutely necessary to have a claim surveyed in order to determine the corner stakes.

IRON DOGS were originally used in placing shaft timbers, the plates being adjusted as nearly as possible and the posts put in place, the whole set being tightened with wedges. The use of hooked hanging bolts has superseded the dogs and are admirable for the purpose. They may be removed when the timbers are firmly wedged and reused below. Where the character of the ground is such that it may be necessary to allow the hanging bolts to remain permanently, a straight bar of the proper length, threaded at one end and provided with a washer and nut and turned at a right angle at the other end, may be employed, the angle being uppermost. Hooked bolts are most convenient for all purposes, but cost a little more.

IT is always best to avoid swelling ground when possible. It is cheaper to sink a shaft through ground of this character than in hard rock, but the expense of keeping the shaft open afterward is constant, and continues as long as the excavation remains in use. There are numerous instances in California mines where excavations made in swelling ground (foliated black slate) have been abandoned, and subsequently encountered by new workings. The only thing to denote that the ground had ever been open before was the rotten timbers found crushed and forced from their original position. When planning a shaft, if any condition indicates the existence of ground of this character it is cheaper and better to sink in either wall parallel with the vein, running crosscuts to it at regular intervals.

FIRE GILDING is done by rolling a strip of pure gold very thin and cutting it in very small pieces. These are placed in a crucible; mercury is added, the gold now being in solution. The work to be gilded is put through an acid dip to clean it, and is then placed in very dilute sulphuric acid. The solution of mercury containing the gold, and which is figured as a certain amount of gold to a pound of work, is then added. The mercury adheres to every part of the work and spreads the gold over the surface. The work is then placed in a cage resembling a peanut roaster, fitted to a furnace at red heat, where it is turned until all the mercury is burned off, leaving the gold it contained evenly spread over the surface of the work. The work is then scratch-brushed and shaded, to get the color, and finished by burnishing.

CINNABAR ORES are treated by roasting in furnaces of peculiar construction, the ore being subjected to high heat without coming in direct contact with the fuel. The mercury is volatilized and condensed in a chamber. The soot from the condensers contains a large quantity of mercury which cannot be squeezed out nor concentrated. It is placed in a cemented trough-like depression, mixed with the wood ashes from the furnaces and stirred with a hoe, which causes the quicksilver to run off from the soot in a stream. This process is discontinued when the quantity of mercury in the sooty material no longer justifies its manipulation. The ore is fed into the furnaces, after drying, at the top and descends to the bottom, where the useless waste is withdrawn, the quicksilver having been driven out. As the charge settles at the top, new ore is charged, making the process practically continuous.

WHERE a mine or other excavation is to be drained by means of a syphon the discharge end must be lower than the surface of the water at all times, for when the discharge end becomes level with the surface of the water the syphon ceases to operate. The syphon may be started by providing it with valves, one at the discharge end and one on the intake end, just below the surface of the water. At the highest point on the line a "T" should be inserted with a short standpipe, which is also provided with a straightway valve. Close both ends and fill the syphon by pouring water into the pipe at the straightway valve. When full close this valve, open that at the intake and then open that at the discharge end, and the water will flow and continue to flow until the weight of the column of water equalizes the atmospheric pressure. The amount of discharge is determined by the size of the pipe. Its highest efficiency would be probably about 25 feet, as above this height the flow would be slow.

IN California the right to the use of running water flowing in a river or stream down a canyon or ravine may be acquired by appropriation; but the appropriation must be for some useful or beneficial purpose; and when the appropriator or his successor in interest ceases to use it for such a purpose the right expires. The person entitled to the use may change the place of diversion if others are not injured by such change, and may extend the ditch, flume, pipe or aqueduct by which the diversion is made to places beyond that where the first use was made. The water appropriated may be turned into the channel of another stream, mingled with its waters and then reclaimed; but, in reclaiming it, the water appropriated by another must not be diminished. As between two appropriators, the first in time is first in right. A person desiring to appropriate water must post a notice in writing in a conspicuous place at the point of intended diversion, stating therein that he claims the water there flowing to the extent of the number of inches he intends to appropriate, measured under a 4-inch pressure, the purpose for which he claims it and the place of intended use.

THE "Washoe process" takes its name from its introduction and extensive use on the Comstock lode, Virginia City, Nevada. This region was originally called the Washoe. The process consists in crushing ore wet with stamps. The pulp is run into settling vats, from which it is shoveled out into grinding and amalgamating pans. In these the charge is heated by steam and bluestone (sulphate of copper), salt (sodium chloride) and quicksilver are added. When amalgamation is complete the pulp is discharged into settlers, where it is thinned by the addition of water and the amalgam settles to the bottom, while the pulp is kept in suspension by the rotation of agitators. Plate amalgamation inside the battery and on outside plates may or may not be practiced. There are several modifications of the process. It is expensive owing to the necessity of handling the material and to the amount of power required to drive the machinery. The "Boss process" is essentially a modification of the Washoe process, its chief feature being the discharge of the pulp from one amalgamating pan to the next throughout a series, forming practically continuous amalgamation.

PEACOCK ore and bornite are the same. Dana's "Mineralogy" gives the following: "Bornite—Purple copper ore; is also called variegated copper and erubescite; called by miners in Cornwall horseflesh ore. It is a sulphide of copper and iron, but varies in the proportion of these metals. The crystallized mineral agrees with Cu_3FeS_3 = sulphur 28.1, copper 55.5, iron 16.4 = 100. Analyses of massive varieties give from 50% to 70% copper and 15% to 6 5% iron; crystallization isometric; habit cubic, faces often rough or curved; massive structure, granular or compact. The fracture is small, conchoidal (shell-like), uneven; brittle; hardness, 3; gravity, 4.9—5.4; luster, metallic; color, between copper-red and brown on fresh fracture, but speedily tarnishes and becomes irridescent (peacock copper ore); streak, pale grayish black; opaque." Chalcopyrite—yellow copper ore—is also a sulphide of copper and iron, which often is tarnished on the outer surfaces, showing brilliant metallic shades of blue green and reddish brown, similar to those observed in peacocks' feathers; but chalcopyrite differs essentially from bornite and rarely contains more than 35% copper. It is the most common copper ore.

UNDER the United States placer mining laws one person may make a single location containing 20 acres of placer mining land, two persons may make a single location containing not more than 40 acres in a compact body, three may locate 60 acres, etc., but no single location, whether made by eight persons or more, can exceed 160 acres. It has been decided that a single location of placer mining ground may embrace 20, 40, 60, 80, 100, 120, 140 or 160 acres in a compact body, according to the number of locators. If eight persons should make eight separate locations of 20 acres each, and seven of the locators should convey their claims to the other, it would require annual assessment work of the value of $800 to maintain the possessory right to all of the claims; but, in the case of a single location, embracing 160 acres of placer mining land, the owner thereof, in order to maintain his possessory right thereto, would not be required to expend $100 worth of mining labor on 20 acres thereof, but his possessory right to the entire 160 acres might be maintained by performing thereon $100 worth of actual mining work designed in good faith for the improvement of the 160-acre location as a single mining claim.

Forest Destruction and Torrent Ruin.*

When man, actuated by greed or ignorance, or a combination of the two, destroys the protection which nature spreads over rolling and mountain areas, he turns loose agencies which soon pass beyond his control. The protecting agent is vegetation, and whether in the form of forests, brush or forage plants and grasses, the balance between it and denuding forests is easily tipped, when the inexorable law of gravity, unchecked by myriad blades of grass, by leaves, roots and vegetable mold, gullies the hillside, strips the mountain slope, converts the rivulet into the torrent, and causes the steady flow of the river to become alternately a devastating flood or a parched sand bed. When once this balance has been destroyed, man cannot turn back the torrent and bid it flow once more a living and life-giving stream.

It would seem that this lesson had been learned so thoroughly by the human race that there would be little use to lay its precepts before a civilized community. But when one goes out over this fair land of ours and marks the rate at which its forests are being destroyed, its mountain forage areas devastated, he is tempted to regret that civilization should be permitted to spread its blight over the temples in which the savage worshiped.

But it must be remembered that this destruction ceases in the judicious use of this wealth of forest and of mountain pasture, and that it is only indifference and incivism which permit greed and ignorance to go unrestrained until they destroy the balance—that man has it within his power to utilize to its fullest measure this wealth and to pass it down to future generations as a blessing, rather than as a blight and a curse—and that he can even aid nature by extending vegetation over barren areas. But this requires that the reckless destruction of forest and the wasteful and continuous devastation of pasture should be replaced by systematic utilization of these sources of wealth.

Probably no range of mountains has longer had civilized man around its base that the great Caucasus and its outliers. This range extends from the Straits of Kertch to the Caspian sea, a distance of over 900 miles. The culminating peak, Mount Elbruz, rises 3000 feet higher than the highest peaks in the United States, and the group is analagous to, but greater in all respects than, the Sierra Nevada. Its slopes drain either into the Caspian sea or into the Black sea and the Sea of Azov. The slope draining into the Black sea is subject to summer rains, and therefore more readily recovers from denuding agencies. The southern slope is broader and gentler than the northern, which is subject to a drier climate, and sparsely covered with both deciduous and coniferous growths. At all points where these mountains were observed man has wrought ruin since the dawn of history. Every stream, every slope, is marked with destruction. The great historic route up the Tirek, through the Darial pass, and down the Gudoor and Arangua to the plains of Asia Minor, is everywhere seamed with the ruin which the unrestrained hand of man has put in force.

In passing along the main drainage lines it is possible, with a little experience, to determine the comparative exposure of the tributary watersheds by the amounts of debris brought down. The illustrations on this page show the general appearance of the slopes and streams, the measures taken to restrain and divert the flow of debris from the roads, and to provide crossings where roads are buried and bridges swept out. Nothing which man can call to his aid can restore soil to these wasted slopes. Such is the penalty of unrestrained stripping of timber and forage plants.

Denudation in Southern France.—In parts of Europe the destruction has been as great. The literature on this subject is both voluminous and accessible. Enormous efforts have been put forth by the European governments to check the destructive force of torrents born upon the denuded slopes of the great chains of mountains throughout the continent. In no instance have these efforts been adequate, although much has been accomplished. Of

INSTANCES OF THE RESULTS OF FOREST DESTRUCTION IN EUROPE AND IN AMERICA.

*Condensed from Sierra Club Bulletin, by M. MANSON.

the deserts of southern France, S. Baring-Gould writes that "one hundred years has sufficed to sweep every particle of soil from the Causses, which it took countless ages to accumulate; and land that once maintained a well-to-do population is reduced to a desert."

In the Rocky Mountains.—In the Rocky mountains the work of devastation has been inaugurated on a scale calculated to dwarf anything done in Europe. Forest fires, the crowding of vast herds of sheep, the ax of the lumberman, followed by the fires of the sheep herder, have all been active agents in converting vast areas into deserts as barren as those of the Causses, the Atlas, or the Apennines. In portions of the Rocky mountains trees spring up rapidly after the first forest fires. Even when these fires have been so fierce as to absolutely destroy every vestige of timber, a second forest springs up with remarkable promptness and vigor; but when this is destroyed the next attempt to restore vegetation is slower and not effective. The cut on the opposite page shows the second year of absolute barrenness in the midst of summer. The areas had been twice swept by forest fires—the first burning off the original timber, the second, following a few years later, killing the sapling firs and pines. Although two summers had elapsed, not a sprig of vegetation had started to clothe for the third time the naked rocky "backone of our continent."

In the Sierra Nevada.—The Sierra Nevada has fared even worse. Around Lake Tahoe the timbered areas have been entirely swept off, with the exception of a few thousand acres around Tallac, and some at the north end, reserved by the owners for later use. The mountain sides around the Hot Springs, and nearly all of the moraines and flats around the south and east sides of the lake, have been denuded. These areas, bereft of timber, are now ready to be abandoned to the State, large tracts being for sale at 50 cents per acre. The railroads, which were constructed to carry logs to the lake, have been torn up, and the region, shorn of its wealth and beauty, has been partly browsed over to give a few sprouts to hungry hordes of sheep.

On the forks of Carson river there are several townships from which every vestige of timber has been stripped, first for mine timbers and later for wood. Then the area was burned over to afford tender shoots for spring pasturage. To-day it is only in rare little patches that young conifers are beginning to gain a foothold, and fires destroy many of these plantations. On the east fork in 1896, after heavy summer showers, the water sluiced off the ashes and soil to such an extent that tons of trout were killed. After the torrent subsided one could drive a four-horse wagon along the banks and fill it with trout. It is doubtful whether the stream can be restocked until the denuded slopes shall be afforested.

Prevalence of Forest Fires.—It is only necessary to read the accounts given in the daily press to partly measure the destruction by forest fires. The writer has personally traced these through every mountain county in California. Even of that area which has been sacredly set aside as the Yosemite reservation, the threat was openly made by the marauding sheep herders, who had devastated Spain and Portugal, that they "would burn the Government out"—referring to the cavalry sent up to prevent the illegal destruction of the vegetation protecting the headwaters of the Merced and Tuolumne. The overstocking of these mountain pastures is what is doing the greatest harm. The writer once asked an intelligent stockman how many sheep could be pastured on a given area in the Sierras, and he gave as his opinion that 8000 sheep could be pastured thereon without injury—that is, without destroying all seed of forage plants and grasses. But, upon naming over the owners and herds which he knew, there were 40,000 sheep accounted for in the area.

The photo-engraving upon another page was taken in the drainage basin of the Mokelumne, California. It shows the path of a so-called "cloudburst." This was nothing more than a heavy summer rain upon a burned-over district, concentrating rapidly in the steep gulches, and finally scouring away timbers, boulders and earth.

Cloudbursts.—In traveling thousands of miles in various ranges of mountains, on three continents, the writer has never seen the track of a cloudburst in a timbered country—always in the barren ranges from which timber was either naturally absent or had been destroyed by human agency. The reasons for this are twofold:

First—Heavy rainfall occurring in a well-timbered country is absorbed, even when the fall amounts to several inches in a short space of time. In a barren region this absorption does not take place; the rain rapidly collects in gulches and forms, in some instances, a veritable wall of water, soil, gravel and rocks, carrying everything before it.

Second—The layers of cold, dry air, and hot, moist air, can superimpose themselves in a treeless country in such a manner that when condensation is inaugurated it takes place with destructive violence. These conditions are modified, or even entirely prevented, by the effects of forests and vegetation; and hence those regions escape the most violent downpours. The rainfall in tropical regions is several times greater than any occurring upon the treeless regions subject to "cloudburts;" yet the destructive run-off from tropical forest areas does not occur, on account of the dense forests and undergrowth.

In Santa Clara county, Cal., the floods of Los Gatos creek have measurably increased in destructiveness. In one of the richest portions of the valley more than $1,000,000 worth of land has been recently destroyed. The engraving on another page shows a portion of this destruction and the feeble efforts of the adjacent land owners to stay the force of the torrential floods which, with increasing volumes, are eating away the alluvial lands, leaving in their stead the "barranca" forms of California.

[The above is from a notable paper by an eminent authority on the subject of forest destruction and its effects. The present wide attention is due to declaration and suggestion, continually urged for years, now impressing the importance of the matter upon the public mind. The agitation which commanded the attention of the Government and led to the establishment of forest reserves bears fruit now in popular attention and interest. No doubt the interest has been hastened and quickened by the recent years of drouth, which have caused a keener appreciation of the value of water supply, but in its present state the question is broader even than the irrigation aspect, as the whole is greater than any of its parts. We have all heard for years of the terrible effects of denudation of European water sheds, the destruction of fertile valleys, the ruin of production and trade and all the sad consequential evils of deforesting the sources of streams. The present presentation of the matter will bring to all a more realizing sense of the evil which has been done and the criminal folly of allowing its repetition in this west half of America. We have no doubt that this will be the conclusion of all our readers when they have studied these views and recalled many like them which they themselves have seen, and a resolution to do what is wise to forfend their recurrence.—ED. M. & S. P.]

Occurrence of Mica in South Norway.*

By J. F. WELLS.

Godfjeld mine is eight miles northwest of Kragero, on the southwest coast of Norway. It was originally worked for feldspar, and subsequently for mica. The rocks of the surrounding country are mica schists, gneisses, hornblende and tourmaline schists. These schists are much broken up by numerous intrusions of eruptive granite dykes of a class usually designated as pegmatite veins. Their strike is northwest and southeast, and they usually dip towards the south, but frequently are nearly vertical. These veins or dykes are of two distinct classes, viz., those which break through or cross the strike of the schists, and those which occur as veins or lenses between the foliations of the schists. The mineral constituents of both are similar, and are essentially the same as those that occur in the granite. Both soda and potash feldspars are present, and are easily distinguishable. The distribution of the minerals is very uneven. In places masses of orthoclase occur both as masses without definite shape and as huge crystals, and adjoining them is always found large quantities of quartz, but, as a whole, the veins are composed of pegmatite, with the pegmatite structure very highly developed. The only mineralogical difference between the two types of veins is the occurrence of many rare minerals in the first named, and their absence in the veins lying parallel with the schistose foliations. At Godfjeld the vein is a large one, varying from 14 to 27 feet in thickness, and having the usual strike and a dip of about 77° with the horizon. The outcrop, however, can only be traced for 200 yards, as at the south end it is covered over by schists, and at the north end it ends abruptly 180 feet above the lake at the foot of the hill.

On the other side of the lake, which is here 200 yards across, the vein reappears, but its character has altered considerably. When it reaches the top of the hill on this side of the lake it runs into a granite outcrop. The strike of the schists in the immediate neighborhood of the vein is at an angle to the strike of the vein, being approximately west northwest, and the dip northeast, but the strike, as a whole, is very variable. The chief mineral contents of the vein are orthoclase, a soda feldspar, quartz and muscovite. Accessory minerals are apatite, tourmaline, biotite, garnet, columbite, orangite, thorite, etc. On the hanging wall side of the vein there was a deposit of milky quartz, of a vitreous and somewhat glassy nature. This quartz did not extend to the hanging wall of the vein, as a whole, but was separated from it by a mixture of the main constituents of the vein, both potash and soda feldspars being present, chiefly the former. This quartz extended along the strike of the vein for a distance of 120 feet, and had the same dip as the vein, but dipped also south at about 45° with the horizon. The thickness varied from 2 to 12 feet. On the foot wall side of the quartz crystals of orthoclase occurred, subtranslucent, and of a pale brown color. The crystals were of a large size, some measuring as much as 4 feet across and 5 to 6 feet high, but this occurrence of feldspar was rather erratic. At times it was remarkably free from other minerals, but it often was full of small mica and blebs of amorphous quartz. As the foot wall was reached it gradually became of worse quality, and finally its place was taken by a soda feldspar pegmatite. This soda pegmatite gradually absorbed the whole vein, the north end of the vein being entirely composed of this pegmatite, which dipped south and finally made its appearance on the surface at the extreme south end of the outcrop. There was a very marked distinction between the two feldspars, not only from a crystallographic point of view, but also in that the two feldspars never seemed to merge into each other, there being not only a difference in color, but often the boundary between the two would be the face of an orthoclase crystal. The cleavage of the soda feldspar was not always apparent. Often it seemed to be in a semi-amorphous condition, enclosing blebs of non-crystalline quartz. The mica (muscovite) which formed a lens or shoot lying between the quartz and the feldspar, or wholly in the quartz, occurred as large crystals, varying in size from a few pounds in weight up to 400 or 500 pounds. This shoot varied in dimensions. At times it extended almost across the vein, but was, as a whole, either between the feldspar and the quartz or entirely in the quartz, and its color was green, but the greater part of the mica had a brown color, due to the numerous stains, rutile enclosures or growths in the crystals. The size of the plates obtainable varied from small pieces up to sheets measuring 2 feet by 1 foot.

Near the surface the mica was much stained, but it improved in depth down to about 50 feet. Very frequently much disappointment was caused by the outside appearance of the crystals, as on splitting them it would be found that they were valueless owing to enclosed garnets, tourmaline and numerous secondary growths of mica. The tourmaline crystals generally were found lying between the cleavage of plates, yet often they penetrated the crystals parallel with the vertical axis. The secondary growths of mica, though usually crystalline, had no definite position of their axes in regard to those of the older crystals. The large crystals of mica had a very interesting but at the same time objectionable peculiarity. The two basal planes were never parallel to each other, and, consequently, the majority of plates split out of the mother crystal were thicker at one end than at the other. At a depth of about 60 feet the character of the mica began to change considerably. Athough there still were crystals which yielded a small quota of plates, the greater part of them were either rotten or so intergrown that they would not cleave, but broke up into flakes. Further, a good many crystals had undergone an entire change, and a greenish, steatitic substance took the place of the mica. This substance gave reactions for alumina, magnesia, potash and silica. In places it was compact, in other places it became earthy, or occasionally fibrous and silky in nature. Shortly after exposure to the air it hardened. This substance did not contain either garnets or tourmaline, though the adjoining mica was full of small garnets. At the lowest place in the workings, a little below the 100-foot level, there was still mica, but it was very rotten and practically of no commercial value. The mica when first taken from the mine was very soft, but after a few months the mica loses this property to some extent and becomes much harder and less pliant.

A few particulars of the other minerals occurring in the vein may be of interest. Apatite in hexagonal crystals occurred here and there. They were often of considerable size, 4 and 5 inches across, and as much as 2 feet in length. They occurred either in the quartz or in the potash feldspar. Tourmaline occurred in all parts of the vein, but never of a quality good enough to be cut into gems. Orangite and thorite (thorium silicate) occurred on the foot wall side of the vein in patches, and these patches usually contained parts of all the heavier minerals occurring. Tourmaline was always present. Traces of copper pyrites were occasionally met with, and the schists in the neighborhood of the mine often carried traces of copper pyrites.

[The above description of a mica mine in Norway is interesting particularly in showing the remarkably coarse crystallization of some of the minerals. In this respect, and also to some extent mineralogically, these veins or intrusions of pegmatite resemble those occurring near Custer City, in South Dakota, where some of these veins have also been worked for mica.—ED. M. & S. P.]

*Condensed from a paper read before the Institution of Mining and Metallurgy.

West Kootenay Ore Bodies.*

NUMBER II.—CONCLUDED.

By R. W. BROCK, Ottawa, Canada.

Natural processes are rarely simple, and the slow process of vein formation is no exception. While replacement of the country rock seems to have been the chief mode, it is highly improbable that there has not been to a certain extent deposition in open spaces—in fact, there is evidence to indicate that this did occur, to a limited degree. In certain parts of some deposits there is a distinct crustification. Now, while it is true that a banding may be and is produced by slight alterations in the conditions during the progress of slow metasomatic change, it may be doubted if a deposit in clear-cut, distinct crusts is ever so produced; so that it is probable that such portions of a deposit have been produced in cavities. Dissolution sometimes may have proceeded in advance of deposition, and thus the space would be produced. But in some cases the ore is found between slickensided walls, sometimes with selvage. This indicates that movement has taken place. As the deposit itself shows no signs of it, it must have preceded the vein formation. It may be that the slickensided walls do not belong to the same fissure, but to two parallel ones, and that the intervening rock has been replaced. But, still, any movement of the walls of an irregular fissure, such as these are, would open up spaces—which might, of course, be partially filled with triturated rock. It is thus altogether probable that some open spaces along the fracture did exist, to be filled by the mineralizing solutions. But in the formation of these ore deposits the process of space-filling seems to be entirely subordinate to the replacement of the country rock.

From the nature of the minerals formed, and from the composition of known thermal springs, one is justified in assuming that the mineralizing solutions contained hydrogen sulphide, carbonic acid, and sometimes, perhaps, sulphates, in addition to their metallic contents. These reagents would account for all the chemical changes involved in the replacement of the country rock and the deposition of the minerals and ores.

The mineralizing solutions, following lines of easiest penetration and substitution, used to a large extent the lines of fracture and crushed zones of the country rock as highways, and as starting points in the formation of the deposit.

Coming from a region of higher temperature and pressure, and charged with the metallic sulphides and active chemical reagents, the solutions would readily attack the crushed and triturated material in these fractures. With chemical activity thus set up, and the nucleus of a deposit thus formed, with a constantly renewed supply of material and reagents from the circulation of the mineralizing solutions, metasomatic action could rapidly proceed.

There should be no prejudice against deposits formed in this way. There is no reason why they should not be as extensive, as valuable, and as permanent as bodies formed in large open fault fissures. Indeed, the history of mining has shown that these great fissures are not as a rule the great producers. To any who may have misgivings about this class of deposit it may be comforting to know that many of the best deposits, especially in western United States, are quite similar in mode of formation to these of West Kootenay.

Thus there is no reason why the ore bodies of West Kootenay should not display permanence in depth. The developmedts in the Whitewater Deep, Payne and Le Roi have shown that the ore shoots here have a considerable vertical dimension. The valleys appear to have been largely sculped after the formation of the ore bodies. Now extensive ore bodies have been found in the deep valleys, thousands of feet below the highest mines, as well as at high altitudes. The surface which existed at the time of formation would be still higher, so that ore was deposited in quantity at great depths below that surface and below most of the present mines. That more mines have not been opened up in the deep valleys is easily accounted for by the difficulty of prospecting owing to the covering of drift and vegetation.

The best and largest ore bodies in any particular district are found in the rocks which are most fractured, as the greater facilities offered by crushed and fractured zones more than compensated for any chemical advantage a rock might possess. As before stated, this might take place in any kind of country rock where the physical conditions were favorable.

Owing to the mode of formation, by replacement following lines of fissured and crushed zones, the forms of the bodies may be very numerous and irregular. In general, they may be said to possess a degree of irregularity corresponding to the degree of complexity of the preceding dynamical effects. To begin with, minor fissures or fractures are usually very irregular. They are usually numerous and coordinated. They may be reticulating; they may be parallel, so that the country rock is sheeted, with or without connecting cross fractures, and perhaps groups of these may be separated by bands of unbroken country rock. But the ore deposition may have been even more irregular. The ore-bearing solution may have followed one fracture for some distance and then have crossed to another, and so on, or it may have followed several parallel ones, and the resulting deposits may or may not be connected with stringers forming what the Germans call "stocke." The ore itself may be found only in certain places in the form of shoots. To further complicate matters, the replacement of the rock along the fractures and crushed zones may not have been uniform. Sometimes, when three or more fissures intersect, the enclosed rock only may be replaced, forming a chimney deposit. Examples of all the foregoing might be given from the Kootenay ore bodies, and if time permitted various other possibilities might be considered. But enough has probably been stated to suggest some practical considerations. It must be evident that no weight can be attached to either the presence or absence of walls. The absence of one or both walls is to be accounted for by the manner in which the rock has been replaced. The presence of apparently well-defined walls may seriously mislead if they are considered as proof that the ore deposition has been confined within their limits, since, however well defined they may appear to be, a crosscut may reveal an adjoining parallel ore body. As an example, reference might be made to an important West Kootenay mine, where the mine manager took great pride in his walls. I tried to show the possibility of there being ore beyond, and the wisdom of judicious crosscutting, and received unexpected support. A shot near one of the walls where it was best defined did greater execution than had been intended, bringing out a large fragment of the wall. This revealed a large parallel ore body apparently equal to or better than the original.

So that in the development of the ore bodies all the attention should not be bestowed on sinking and drifting; judicious crosscutting may sometimes be advisable. At Butte and in many other mining districts in western United States, where similarly formed deposits occur, this principle of crosscutting even where there are apparently good walls is practiced often with great success.

Further, should a good ore body apparently discontinue in depth, it may be that a little exploiting might reveal its downward continuance along another plane. Another point which is apparent is the advisability of following ore. In a highly mineralized locality even little stringers may lead to bonanzas.

In addition to the dynamic activity prior to the vein formation, which resulted in the complex fracturing of the country rock, and which prepared the ground for the mineralizing solutions, there have been subsequent movements which have caused minor displacements, both normal and reversed.

Since the ore bodies show great complexity, but are dependent more or less upon the fracturing of the country, and since matters are further complicated by subsequent faulting, it is evident how important it is that the mining engineer should make a careful study of the structural geology of his district, for by this means alone can a correct notion be obtained of the mode of fracturing of the country which prevails, of the ore body, and of the character and extent of the faulting. In the study of the latter he will find the dykes of great assistance, as they are numerous, clean cut and easily recognized, and, as many are as old as the deposits, these must have undergone the same displacements. He will also find that the smaller veinlets will often afford the key to the solution of problems which his larger, intricate ore body will not disclose.

On a prospect where the trend of an ore body is not definitely proved it is obviously dangerous, instead of following the lead, to spend money on work which will be of value only if the ore body happens to follow a particular direction. To point to the number of shafts and tunnels on prospects in the Kootenay which have eaten up the prospector's capital, while proving absolutely nothing regarding the deposits, is all the comment that is needed on this point.

The light porphyry dykes, to which attention was called while speaking of the rocks, appear to be closely related to the ore deposits. They are abundant in richly mineralized portions of the district, and are conspicuously absent in such portions of the district as on parts of Midge, Cultus and Summit creeks, where no deposits of value have as yet been found. That the dykes and ore bodies should be so associated appears to be more than a mere coincidence.

In the portion of the district in which I was working last summer between Slocan and Arrow lakes, I found that almost without a single exception, wherever a deposit of mineral was observed, it was in the immediate vicinity of a dyke, frequently along the contact, or, if not, in fractured country rock close by. Later on in the season, when on the North Fork of the Salmon, near the head of Burnt creek, it was found that the claims ranged along a dyke. The prospectors inquired about the influence of the white dykes, stating that wherever mineral was found in that portion of the district, it was in the neighborhood of the dykes.

I had no time to verify this statement except at the one point. Before the season closed a visit was paid to the mines around Sandon.

Here, as elsewhere, the same relationship between the dykes and ore bodies appeared to exist. A habit was formed of asking for the white dykes on a claim, as naturally as for the lead. I think in every mine visited were not only dykes seen in the vicinity, but one or more could be found in the workings themselves. Most of the observant managers considered the white dykes to form part of the deposit. One or two claimed that proximity to the dykes influenced the tenor of the ore. Even if the dykes could not be observed in or near every mine, this would not necessarily disprove the relationship, as they might be close at hand, yet not exposed at the surface or in the workings.

It is quite probable that the volcanic activity which resulted in the injection of the white dykes may have been the cause of much of the fracturing or fissuring of the country rock, and thus of the production of the highways for the mineralizers. The white dykes themselves do not show this shattering. It is now generally accepted that eruptive rocks, especially acid eruptives, thermal springs and ore deposits, are intimately related in their origin. It is an observed fact that the closing stages of a period of volcanic activity are marked by solfataric action, the emission of thermal mineral-bearing waters. Now, as before stated, the West Kootenay deposits were formed by the direct agency of such hot mineral-bearing solutions. It is not improbable, therefore, that these were connected with some eruptive. If this were the case, it would be with the porphyries, as these mark the last period of volcanic activity which preceded the formation of the deposits. Moreover, the dykes themselves show evidence of sofataric action in the alteration they have often undergone. The feldspars are altered and calcified, so that it is sometimes difficult to make out the structure of the rock. Pyrite has been formed—often probably at the expense of what colored constituents the rock possessed. An interesting point with regard to these dykes is that they are to some extent auriferous. Profs. Nicol and Miller, of the School of Mining, kindly assayed three samples. They were small samples selected as rock specimens, one from a dyke in the Last Chance mine, Sandon, one from the North Fork of the Salmon, and one collected by Mr. McConnell from the Antelope claim. The last proved barren, but the Last Chance and North Fork rocks yielded distinct colors of gold. Considering the small quantity taken for assay—two assay tons—the result is very interesting.

From the evidence so far available, I am inclined to favor the view that the solutions mark the solfataric stage in the period of vulcanism, during which were erupted the white dykes. On the other hand, it might be claimed that the solutions came from depth and merely used as highways lines of weakness often occupied by the dykes; or mineralization might be considered by some to be due merely to the increase in physical and chemical activity in the existing circulating currents, caused by the heat of the eruptive.

But such speculations as to the precise way in which the dykes and ore bodies may have been related, while extremely interesting, are not of direct economic importance, and need not be here further discussed. The point of practical value to be established is that the relationship does obtain. If this can be done, the value of such well defined and striking bodies as these dykes as guides in prospecting and developing would be inestimable. While the observations made last summer, particularly in the mines, were not sufficiently extensive to warrant one in definitely asserting that such a relationship obtains throughout the entire district, yet they covered a comparatively wide field, and in many cases were of so positive a nature as to justify the conclusion that, in those particular instances, at least, the dykes and the ore bodies were related. But the strongest evidence probably is the fact, to which attention has already been called, that the districts rich in dykes are rich in ore bodies, and those barren of dykes appear to be barren of ore.

The attention of mining engineers is called to the matter in hope that they will test the point in various parts of the field, for it is only when supported by observations in the mines and prospects of the entire district that it can be considered definitely established for the West Kootenay district.

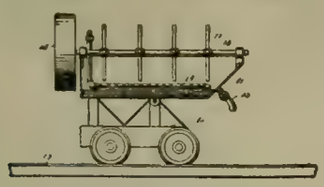
In a great many mining districts throughout the world such a connection between dykes and ore deposits has been observed. At Pontgibaud, in Auvergne, silver-lead occurs in gneiss and mica schist dyked by porphyry; the lodes generally follow the dykes and are productive only when so associated. In the silver-lead deposits of Eureka, Nev., the ore-bearing solutions were almost entirely due to solfataric action arising from the eruption of rhyolite, which dykes all the formations. The rhyolite dykes show every evidence of solfataric decomposition. Hague, in speaking of the same district, states that after a careful study he is forced to the conclusion

* Condensed from Transactions Canadian Mining Institute.

that there exists the closest relationship between the rhyolite and the formation of the ore deposits.

In speaking of the relationship between the deposits and the eruptives in the Mercur district, S. F. Emmons says that in searching for gold in that district the first thing to do is to learn to recognize in the field the porphyry in its many forms of alteration, and then gives rules to be observed in prospecting, based upon the relationship which exists between the ore bodies and the eruptive.

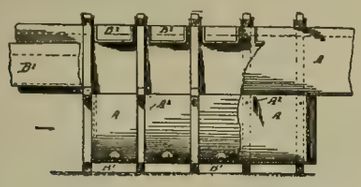
Blow, in a paper on Iron Hill, Leadville, Colo., states that, as a guide to future developments on Iron Hill, it may well be noted that wherever a dyke (of porphyry) of considerable size has been hitherto disclosed, an ore body of proportionate size has been encountered following it.



It will be seen that the West Kootenay ore bodies bear a strong resemblance to many in the western United States.

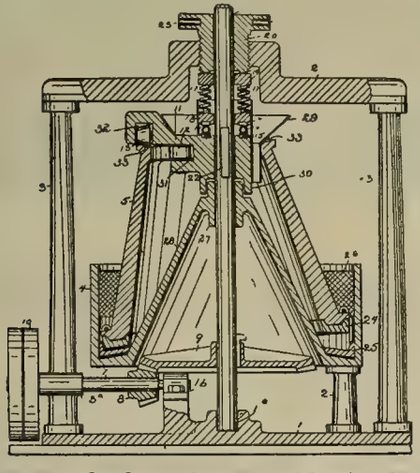
Latest Mining and Metallurgical Patents.

Patents Issued Aug. 15, 1899.



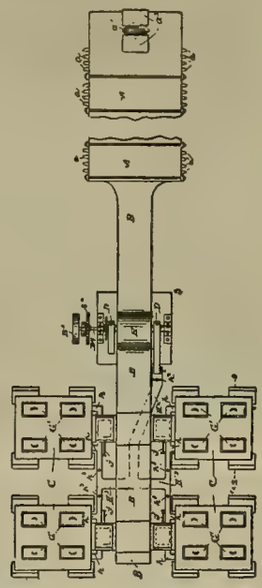
Specially Reported for the MINING AND SCIENTIFIC PRESS.

PROCESS OF SEPARATING PRECIOUS METALS FROM ORES.—No. 630,842; W. H. Baker, Deadwood, S. D.



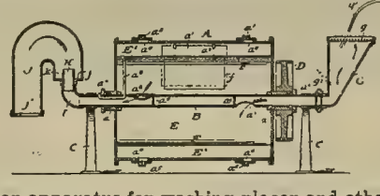
A process of separating precious metals from ores, consisting in subjecting the ore to the action of a cyanide of potassium solution, admitting steam to the mass to bring it to the boiling point, agitating the same, separating the solution, adding water to the tailings, utilizing the resultant solution for the generation of steam to heat the cyanide of potassium solution, subjecting the tailings to which water has been added to the action of heat while being agitated, separating the solution, adding more water to the tailings and then separating the resultant solution and utilizing the same in the treatment of a fresh supply of ore.

SLUICE, RUNWAY, OR FLUME.—No. 630,971; P. S. Buckminster, San Francisco, Cal.



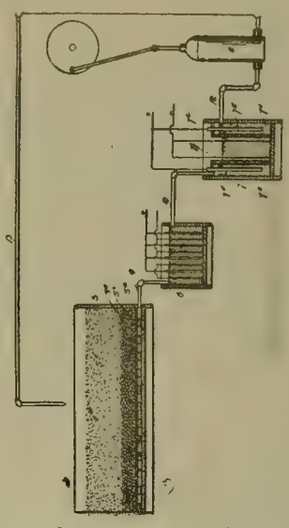
The combination with a sluice, runway, or flume having a portion of its bottom removed, of a V-shaped receiving or settling chamber arranged longitudinally below the sluice, runway, or flume at the point where bottom is removed, a series of transverse pieces in receiving or settling chamber for checking the current and preventing an undercurrent, a controlled discharge opening in receiving or settling chamber, an auxiliary flume arranged beside the main flume, and a discharge from the upper part of the main flume to the auxiliary flume.

ORE PULVERIZER.—No. 631,236; H. M. Williamson, Denver, Colo.



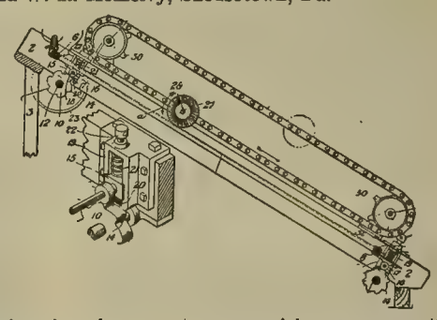
A pressure head carrying an anti-friction device which bears on the top of the grinding muller or shell and also carrying means, horizontally in contact with the muller adapted to give the latter a gyral motion as the head rotates, in combination with the muller, the pan in which it works to grind the ore, the shaft on which the head is slidingly feathered, and means for forcing the pressure head downwardly by yielding pressure applied thereto vertically. In combination with a pan and a grinding muller operating therein, a shaft extending from the bottom to the top of the machine, a pressure head attached to the shaft and rotating therewith, horizontal and vertical rollers journaled in and carried around by the pressure head and arranged to give the muller a gyral motion, and springs arranged about the shaft and bearing vertically on pressure head at points on opposite sides of the shaft. A pressure head 11 provided with recesses 31 and recess 32 in the under side of one end, and bored and grooved vertically, in combination with a shaft having splines or feathers fitting in the grooves of the bore, springs which bear on the pressure head to force it downward, vertical and horizontal rollers turning in the recesses, a grinding shell having its upper end arranged for contact with the vertical and horizontal rollers, and a pan in which the grinding shell operates on the ore or other material as it is gyrated by the rollers.

GAS PRODUCER FOR METALLURGICAL PLANTS.—No. 630,885; E. C. Hegeler, La Salle, Ill.



A metallurgical plant comprising a combustion chamber having a gas escape opening at one end and means for varying the size of the opening whereby to regulate and fix the pressure in the chamber, a gas producer having feeding and stoking openings and means for closing the same, and draft openings beneath the fire box with means for regulating the draft thereto, thereby to establish and maintain an equilibrium of pressure of the gas in the producer with the outer atmosphere at the feeding and stoking openings and to deliver gas under pressure at the same, a flue directly connecting the combustion chamber and the producer, and a blower in the flue intermediate of the combustion chamber and the producer for drawing gas from the producer and forcing it uncooled and under pressure into the combustion chamber, also retarding or promoting movement in the producer according as there is tendency to produce more or less than the required amount of gas, and, further, simultaneously operating upon the draft in the producer both above and beneath the fire and at points in opposite directions from the feeding and stoking openings.

APPARATUS FOR WASHING PLACER SOIL.—No. 631,020; S. M. Lissau, Philadelphia, Pa.



In an apparatus for washing placer and other soil, a rotatable drum, a cylindric diaphragm of foraminous material in drum, normally closed openings in the drum and in the diaphragm in line with each other, a hollow shaft upon which drum is mounted, a plug or stoppage in the central portion of shaft, a lateral screen-provided opening in shaft on the discharge side of stoppage or plug, means for supplying the water to one end of shaft, a vertical extension in communication with the other end of shaft, a goose-neck formed of pipe of greater diameter than vertical extension, and one end of which incloses the upper end of vertical extension to form a settling chamber, a hopper the discharge end of which leads into axle, and an air vent pipe one end of which opens within the cylinder, the other end of which opens outside the cylinder and the intermediate portion of which extends within the hollow axle.

PROCESS OF EXTRACTING PRECIOUS METALS FROM THEIR ORES.—No. 631,040; J. E. Greenawalt, Denver, Colo.

A process for the treatment of gold and silver ores which consists, first, in properly roasting the pulverized ore; second, in placing the ore in a filtering vat; third, in passing through the ore an electrolyzed solution consisting of a solution of chlorides, chiefly sodium and ferric chlorides, and small quantities of chlorine and hypochlorous acid, with such other compounds as result from the electrolysis of a chloride solution; fourth, passing the solution after it leaves the ore through a precipitating tank; fifth, passing the solution after it leaves the precipitating tank, through the positive or anode compartment of an electrolytic cell keeping the solution separate and distinct from the solution in the negative or cathode compartment in the cell; and sixth, returning the solution from the regenerating cell to the ore in the vat, and passing it again to the precipitating tank, again to the regenerating cell, and again to the ore as often as may be required to effect the necessary saving of the values.

MINERAL SEPARATOR.—No. 630,926; W. E. Porter and W. R. McKelvy, Shousetown, Pa.

A mineral separator comprising a supporting framework set at an angle, cross-shafts mounted therein, cams secured on shafts, a screen mounted on cross-shafts having sliding bearings in the frame provided with elastic cushions and rollers on the cross-shafts adapted to be engaged by the cams; the cross-shafts driven at different speeds, cams secured on shafts, a screen mounted on cross-shafts having sliding bearings in the frame provided with elastic cushions and rollers on the cross-shafts adapted to be engaged by the cams.

WET PROCESS OF EXTRACTING SILVER FROM ITS HALOID SALTS.—No. 630,951; L. Vanino, Munich, Germany.

The wet process of extracting silver from its insoluble haloid salts which consists in mixing haloid salts with a watery solution of alkaline agents and adding formic aldehyde in the cold.

PROF. JUELLIG, on the maximum possible spans for overhead wires of various materials, bases his calculations on a factor of safety of four. With wire drawn from cast steel, he found it possible to use a span of nearly 3½ miles, while with silicon-bronze the maximum span varied from 1½ to 2 miles, according to the composition of the alloy. With wrought iron wires the maximum span was just over a mile, while with soft copper wire half a mile is the limit.

THE last five of the twenty new open-hearth furnaces erected as an addition to the Carnegie Steel Works at Homestead, Pa., were blown in Aug. 10th. Four additional furnaces are being built.

Liquid Air.

Of what use is liquid air likely to be? This is a proper question, and yet, if scientific workers always stopped to ask it, and would not work unless they could find a favorable answer, progress would be much slower than it is. Most great practical discoveries have necessarily passed through the plaything stage. Some of the most important discoveries have not even furnished playthings, and have found no practical applications as this expression is commonly understood. But the production of liquid air, while furnishing mankind with a beautiful and instructive plaything, seems likely to find practical applications. We may look for these in four directions:

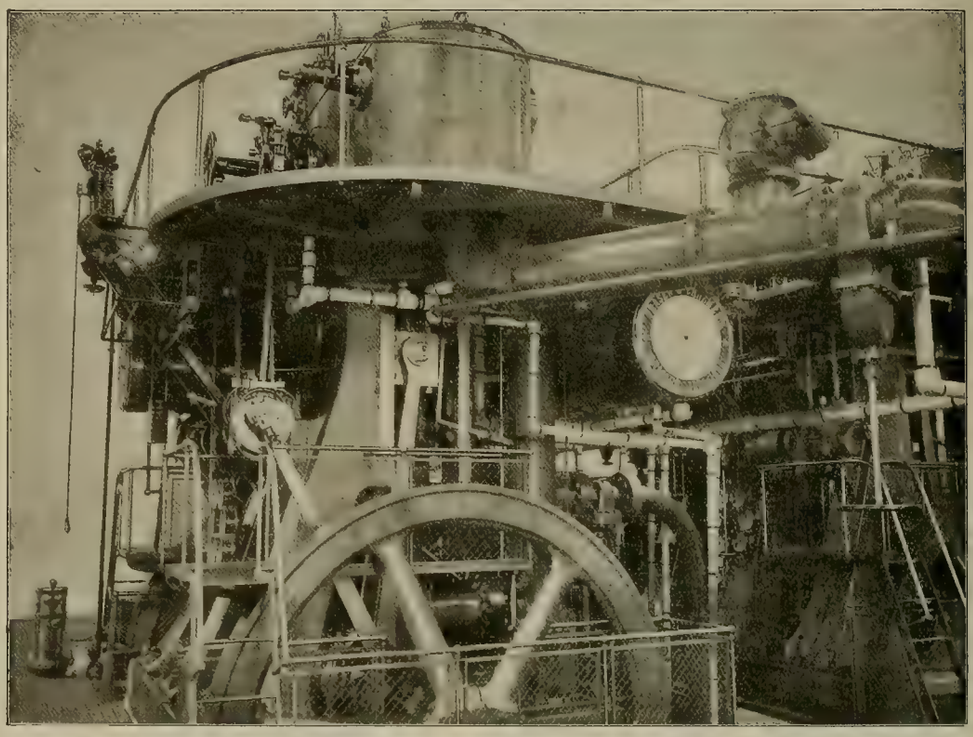
First, as a cooling agent. Low temperature is marketable. To be sure, the demand for the extremely low temperature that can be produced by liquid air does not exist to-day, but this concentrated low temperature can be diluted to suit conditions. The only question to be answered in this connection is, then, What is the cost of cold produced by liquid air? It is impossible for anyone to answer this question satisfactorily at present. It can only be said that this is what experimenters are trying to find out. It appears, however, that they are on the way to cheap liquid air, and that as the processes are improved the price will become lower.

Second, for the construction of motors. There is no doubt that liquid air with its power of expansion can be used as a source of motive power just as compressed air is. In the case of steam it is necessary to heat water in order to convert it into steam, and to heat the steam to give it the power of expansion. The cost is, in the first instance, that of the fuel. Given a certain amount of heat, and a certain amount of work is obtained. If liquid air is used, the problem is much the same. Engines must be run in order to compress the air which is to be liquefied. Every gallon of liquid air has been produced at the expense of work of some kind. The question is, What proportion of the work that was put in that gallon of liquid air in its production can be gotten out of it again? It is certain that all of it cannot unless all that we have ever learned about such matters goes for nothing. In dealing with the problem of the application of liquid air as a source of motive power we are, therefore, doubly handicapped. We do not know the cost of the liquid when produced on a large scale, and we do not know the probable efficiency of a liquid air motor. Perhaps Mr. Tripler and the others engaged in the experiments on this subject know approximately. We certainly cannot blame them for not telling us all they know. It is unfortunate, however, that such a statement as was recently published in a popular magazine should be allowed to gain currency—apparently with the sanction of Mr. Tripler—to the effect that ten gallons of liquid air have been made by the use of three gallons of liquid air in the engine. If that means that ten gallons of liquid air are made from air at the ordinary pressure, the statement is in direct conflict with well-established principles. If it means that the ten gallons of liquid air are made from air that has already been partly compressed, we must know how much work has been done before the liquid air engine began. Leaving out of consideration the question of cost, it may be pointed out that liquid air engines would have the advantage of compactness, though they would necessarily be heavy, as they would have to be strong enough to stand the great pressure to which they would be subjected.

The third application of liquid air that has been suggested is in the preparation of an explosive. In fact, an explosive has been made and used for some time in which liquid air is one of the constituents. When the liquid air from which a part of the nitrogen has been boiled off is mixed with powdered charcoal, the mixture burns with great rapidity and great explosive force. To make this explosive, Dr. Linde pours the liquid containing 40% or 50% of oxygen on fragments of wood charcoal, two or four cubic millimeters in size. These are kept from scattering by mixing them into a sort of sponge with about one-third of their weight of cotton wool. Of course, this explosive must be made near the place where it is used. It has been used in the way of a test in a coal mine at Pensburg, near Munich. The chief advantage of the explosive is its cheapness, and the fact that it soon loses its power of exploding.

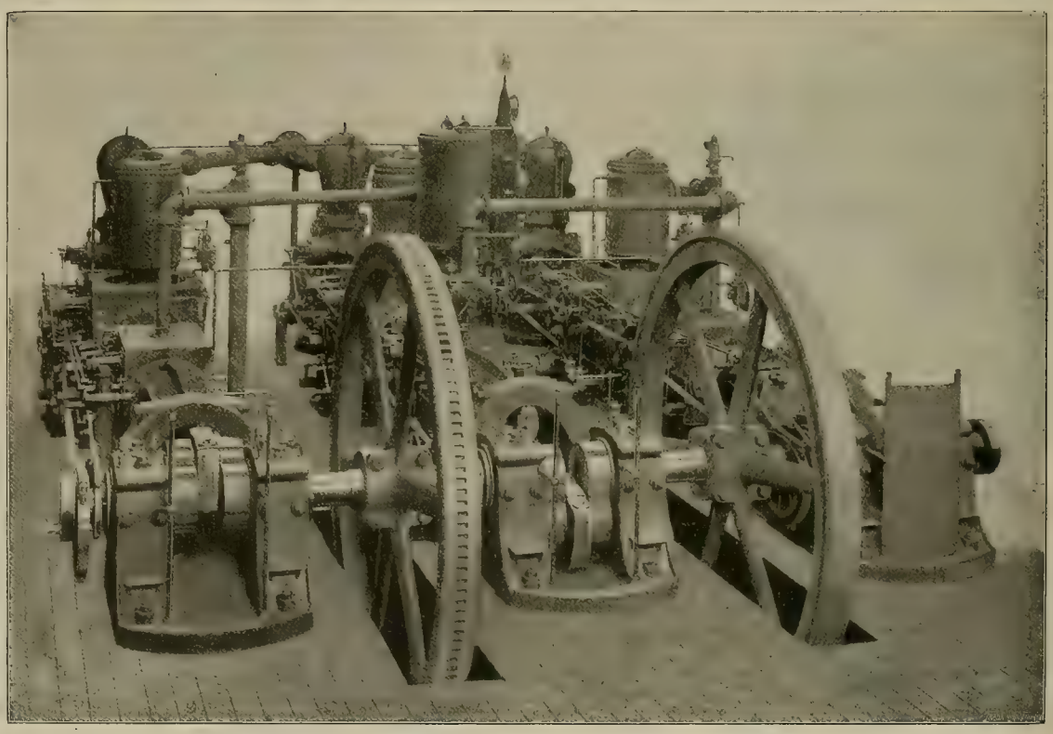
The fourth application of liquid air is for the purpose of getting oxygen from the air. This can be accomplished by chemical means, but the chemical method is expensive. Oxygen has commercial value, and cheap oxygen would be a decided advantage in a number of branches of industry. It will be observed that it is the liquid oxygen that makes possible the preparation of the explosive described in the last paragraph. Oxygen as such in the form of gas is of value in Deacon's process for the manufacture of chlorine. In this process air and hydrochloric acid are caused to act upon each other so as to form water and chlorine. The nitrogen takes no part in the act, and it would be an advantage if it could be left out. It is only the oxygen that is wanted.—Popular Science Monthly.

High-Lift Pumps.



To the Editor:—Permit me to cite a few cases where pumps are lifting large volumes of water to great height:

At the Mansfield copper mines, in Europe, three pumps have a capacity of 17,000,000 gallons or more in twenty-four hours, lifting water 950 to 1000 feet. A large pump at Felsenkirchen, Germany, has a lift of 2000 feet, and three at Kladno, Austria, have lifts of 1600 to 1700 feet.



The most remarkable pump in the world is at the works of the Bethlehem Steel Co., South Bethlehem, Pa. This pump has been in service many years. It will pump more than 1,300,000 gallons a day against 7000 pounds pressure per square inch, being used in connection with their armor-plate press. Of course, head or pressure is the chief consideration, volume being at most merely a matter of duplication; this pump not only has a large capacity, but lifts against a pressure equivalent to a head of over 16,000 feet, say, three miles, which dwarfs the 900 feet proposed for the Rand. C. P. Coleman, purchasing agent for the Bethlehem Co., says: "The pump is the most powerful engine on land in the world, and is working every day. It has given very satisfactory service."

At the works of the Pope Mfg. Co., Hartford, Conn., are two pumps having a capacity of over 1,500,000 gallons against a pressure equivalent to 2760 feet head. At the Chapin iron mine are pumps built to lift 3,168,000 gallons a day against 1700 feet head. These two last mentioned were built by Fraser & Chalmers of Chicago, Ill., and the accompanying illustrations of them are of interest.

Oak Park, Ill., July 31st, '99. C. H. Fitch.

TRIPLEX SINGLE ACTING VERTICAL RIEDLER PUMP.

TRIPLEX DIFFERENTIAL RIEDLER PUMPING ENGINE.

Leadville, Colorado, papers are devoting considerable space to the exposure of the operations of an alleged mining company, the High Five, supposed to own and work mines on Breece hill in that camp. They say that the most persistent search and inquiry have failed to locate the High Five, which is a dividend payer. The natural assumption is that Eastern people who are buying stock are being swindled. It is the duty of newspapers and of citizens, whether in office or out, to expose frauds of this character as fast as they appear.

Mining Summary.

ARIZONA.

GRAHAM COUNTY.

The Detroit Copper M. Co. will build a narrow gauge railroad from Morenci to connect with the Arizona & New Mexico Railroad at Guthrie, twelve miles below Clifton. The road will be eighteen miles long and will be extended from Morenci to the concentrator, now under construction by the Detroit C. M. Co. near Morenci.

Tombstone *Prospector*: Work has been resumed on the Tranquility mine and the twenty-five miners are again employed.——The King of Arizona mine was started last week, but compelled to shut down for a few days owing to some difficulty with the pump in the deep well.

YAVAPAI COUNTY.

(Special Correspondence).—In the Jerome district the most important deal of the last week was the bonding of the Farwell and Divide mines, owned by C. Harryhouser, to J. M. Evans, purchase price to be $24,000, bond to expire Jan. 1, 1900. Eight hundred dollars was paid down. The mines are north of the United Verde smelter, and, while not claimed to be an extension, are believed to contain good ore.

J. W. Dean, Mgr. of the United Verde Jr. Copper Co., has returned to Jerome and announces that he will remain and push development work, with the aid of Supt. Wallace. A new road has been made into their property, which is intersected by another new road to the mines of the Decatur Co. The Decatur people are active and are stimulated by the visit of C. W. Devore, chief of the fire department of Decatur, Ill., who is a large owner in the enterprise. Most of the stock in this company is held by Illinois people.

The Ellnor Gayle spring, near Equator hill, the property of H. J. Allen, is being developed and the water will be piped to the United Verde smelter. Nine miles of 6-inch iron riveted pipe, costing over $25,000 when delivered, has been ordered for the purpose.

The News mine operated by H. E. Owen, formerly of Los Angeles, has added another large boiler to the plant.

The United Verde Extension (G. W. Hull) has removed the water from the shaft and drift of the 1888 and is sinking on the Jerome claim of the same group. The hoisting machinery is on the ground. The shaft is being retimbered.

Supt. Hendy at the Copper Chief is sinking his shaft. It is down 140 feet and is in sulphides.

On the Iron King (also Equator hill) a road is being built to connect the new tunnel with the main roadway. A compressor to be run by water power will be put in and the tunnel will be driven to the ledge.

The Equator litigation, which has continued for ten years, is about to be settled. A compromise was effected some months ago and the papers are to be signed this week. W. A. Clark of Montana, John Duke, J. L. H Hendy, Farrell and others were parties involved. By the agreement Clark takes the Iron King and a few other claims and half the water of Silver spring, while his opponents take the Copper Chief and other claims and the other half of the Silver spring flow. One party calls their group the Copper Chief and the other the Iron King. Experts have testified in court that $30,000,000 worth of copper is in sight in this property. HERBERT ALLAIRE.

Jerome, Aug. 17th, '99.

A prospector who has been at work on English gulch, three miles south of Prescott, from which a large amount of placer gold was obtained in early days, has found a small vein near the head of the gulch which is rich in gold, and it is thought may be the principal source of the gold in the gulch, no other vein having ever been found. He will crush the rock in an arrastra.

The Vulture mine, fourteen miles southwest of Wickenburg, is being operated by the New Vulture M. Co. A 100-ton cyanide plant has been in operation for three years on tailings, during which time three acres have been worked. The tailings cover forty acres to a depth of 15 feet. The mine is being reopened and furnished water for cyaniding operations. The mine has an 80-stamp mill. In new workings in the west end of the property sulphide ores are found, a portion of which is shipped to the El Paso smelter. G. Saunders is Supt.

The Garcia mine, near Wickenburg, is being reopened by the Garcia G. M. Co., a Canadian corporation. The mine has a 5-stamp mill.

At the Gold Bug, east of Wickenburg, a crosscut tunnel 100 feet has reached the vein and a drift run 130 feet in the foot wall at the side of a vein 3 feet wide. A winze has been sunk below the tunnel level in ore. A raise will be made to the surface, and this will then become the main working shaft; a hoist will be put on. W. H. Stevens is the owner.

A. O. Brodie, Supt. Crown Point mine, twenty-two miles east of Wickenburg, will put a gas or oil hoist on that property. The ore will be hauled to the summit of a ridge near the railroad and piped from a tank located there to the mine.

The Trilby mine, east of Wickenburg, is down 250 feet, and a new shaft has been sunk 60 feet and sinking. The ore carries free gold and auriferous sulphides. The latter are concentrated and shipped.

The Congress mine is working and the 40-stamp mill running. Some new work is being started, which is reported to have developed rich ore. The cyanide plant is treating old tailings and also those coming from the mill.

Nine miles east of Wickenburg, the old Oriole mine, which was formerly worked by Mexicans, who crushed the ore in arrastras, is now being worked by F. White and is known as the Ardath. He has a 5-stamp mill, with an extension for five more. Water is being developed in a well near the mine.

YUMA COUNTY.

It is reported that the Harqua Hala mine, bought last week by the former owner, Mr. Hubbard of Redlands, Cal., is to resume operations with C. Pickenbeck in charge.

The breaking of the pump at the King of Arizona has caused that mine to shut down. The mine depends for water supply on the pump, which is at the wells several miles from the mine.

CALIFORNIA.

Amador.

There is a report that the McIntyre and South Spring Hill mines, south of Amador City, are to be consolidated.

Jackson *Dispatch*: A test crushing of 186 tons of ore taken from the Central Eureka mine, near Sutter Creek, made at the Zella mill, yielded $13,466.93 free gold. Of the rock crushed 146 tons were from the shaft, which is down 1500 feet, and 40 tons were from other parts of the mine. There are four and one-half tons of sulphurets which will yield $200 to the ton. The Central Eureka is south of the Eureka or Hayward mine and the character of the rock is much the same. W. R. Thomas is Supt.——The East or new shaft of the Kennedy is down over 500 feet and is sinking 20 to 25 feet a week. Twenty-five men and four power drills are working in the shaft. At the old works rock is hoisted from both shafts and the 40-stamp mill is running.——At the Argonaut ore is being hoisted from every level from the 800 to the 1500-foot, and the 40-stamp mill is steadily crushing pay rock.——W. A. Cole, Supt. of the Sunny South mine, near Volcano, reports the shaft on his mine is down 75 feet and prospects good.——Mr. Joyce of the Defender mine, adjoining, is sinking. The shaft is down 130 fee', with good ore in the bottom.——Mrs. A. Boro has commenced action against T. Chichizola in the Superior Court to compel defendant to execute and deliver a certificate of redemption for the Gover mine, north of Amador City, plaintiff having offered defendant $2800, which he refused. The Gover is one of the largest mines in the county, but is low grade.

Calaveras.

The work of pumping the water out of the Lockwood mine, two and a half miles southeast of West Point, will be commenced in a few days. The mine has been bonded to San Francisco parties, who are at the mine with all necessary supplies. The Lockwood was formerly a producer. The vein occurs in grano-diorite and is typical of mines in granite in California.

Mokelumne Hill *Chronicle*: The Empire copper mine at Copperopolis, owned by C. Braids, has been transferred to the Ames estate of Boston, owners of the Union mines. The Empire is one of the principal mines of the group. C. D. Fontana and M Ross, agent for the Ames people, made the deal. The Empire mine carried with it nineteen and three-quarter acres in Copperopolis. The price paid by the company was $60,000. Braids got $27,500 and the difference was made by Fontana and others.——The Gladiator mine on the Mokelumne river has been sold to Mr. Posey, a Colorado capitalist and owner of the Tom Boy mine.

San Andreas *Citizen*: It is locally reported that the Ford mine at San Andreas is to be started up by the middle of September. The mine is down 700 feet with levels at 300, 400 and 700 feet. While these are being exploited the main shaft will be sunk below 1000.——C. Nuland, of El Dorado, has sold his quarter interest in the Good Hope, north of the Gwin mine, to J. Raggio.——The Fellowcraft, at San Andreas, which has of late been worked by the Veritas M. Co., has been shut down, and the miners given time checks for a portion of the money due them.——At Campo Seco the copper mines are being reopened after a long idleness. One furnace is in operation and machinery is going into that section.——D. Bailey, of Camanche, is developing the Chris Anderson gravel mine.——A Fresno corporation, known as the Cherokee M. Co., has been organized to work the Cherokee mine at Altaville, held under a bond from B. R. Prince. The mine is to be reopened.——The Lucky Boy quartz mine, located four miles south of San Andreas on the Copperopolis road, has been sold by J. Waters to a Boston syndicate for $10,000; $1000 was paid down. The negotiations were made through U. J. Hussey and F. J. Eastman of Boston. The new owners will put on a steam hoist to sink 500 feet. Work is to begin within thirty days.

Del Norte.

Crescent City *Record*: Crawford & McGowan in two weeks have taken out, sampled, sacked and shipped 110 sacks of high-grade copper ore from their mine on Myrtle Creek hill. Shipments of ore are being made weekly from the several mines and all are producing results.

El Dorado.

The Cambrian mine, which has been shut down for several weeks for the purpose of adding more stamps to the mill, has resumed work.

Placerville *Nugget*: A light fall of snow is reported on the summit of the Sierras.——The Colorado Con. and Baltic mines in Sly Park have started up.

Democrat: From a twenty days' run with an arrastra on his mine near Fairplay, W. F. Lupold cleaned up over $200.

Georgetown *Gazette*: It is reported that the hoisting works at the Esperanza, Garden Valley district, will be removed to the Big Chunk mine, Kelsey district.——A cave 40 feet square occurred recently in the road near the mill at the Taylor mine.——Development at the St. Clair mine, Kelsey district, is progressing. The shaft is down 80 feet. Six men are employed.——A mill test of fifty tons of rock from the Little Gem mine, near Josephine, is being made at the Esperanza. The ledge of ribbon rock averages 20 inches, and gold can be seen in the rock. Ten men are employed. If the mill test proves satisfactory a mill will be built on the property.

Fresno.

A strike is reported on Big creek, forty miles from Fresno, by M. G. York. The place had been prospected before, but only surface work done. York went down to bedrock.

The S. P. Placer M. Co. has been incorporated by R. S. Bodman, W. Hamilton, F. and J. M. Coburn of Los Angeles; J. S. Carroll, H. Russell, W. and E. Fletcher of Fresno; J. Massie and G. Fillmore of Oakland; capital $200,000.

Kern.

J. G. Stahl of Ross Station has contracted with F. M. Smith of Oakland to haul 250 tons of borax from near Frazier mountain in this county to Lancaster, on the Southern Pacific. The borax deposit is said to be extensive. The exact location is southwest of Frazier mountain. It lies in dry lakes and ledges.

In the Randsburg district much of the richest ore in other camps would be considered valueless, judging from its physical appearance. The ore is the result of alteration of the original country rock along the plane of a fissure or zone of fissure planes. The rock has been crushed and altered, but in many instances still retains the original crystalline structure of the rock from which it is altered, although containing much silica. The ore is a light gray tinged with yellow. Some of the best ore from such mines as the Butte and Wedge shows no gold, but, upon being pulverized and washed, shows a quantity of coarse gold.

Randsburg *Miner*: The Yellow Aster Co. have put men to work at the wells to develop more water. The water supply is plentiful for present needs; but if a sufficient quantity can be developed, more stamps will be added to the mill. The machinery is on the ground for the machine shops. H. J. Woollacott, Treas. Butte Lode M. Co.; A. Jacoby, Vice-Pres.; C. F. Howland, Sec'y; Dr. C. B. Dickson, director, all of Los Angeles, have been visiting the mine. A cleanup of thirty tons of ore from the Butte mine at the Red Dog mill returned $1000. They will add hoisting machinery and erect a mill at the mine as soon as development justifies it.

Bakersfield *Echo*: At the Warrington mine, near Havilah, a strike is reported and the vein is proving rich. The mine is employing twenty men and will add fifteen. The company's mill is soon to be increased to fifteen stamps. They have 30,000 tons of low-grade ore on the dumps that will run $4.50 to $7 a ton. They also have a cyanide plant. Other mines around Havilah are looking well. The Warrington is being operated by an Eastern company.

Los Angeles.

There are veins of lead-silver ore and of dry silicious silver ore on Santa Catalina island, off the coast of California. The lead-silver veins were worked in a small way years ago by a man named Gardener. It is said some of the ore shipped from the veins at the isthmus on the island assayed $100 per ton. There is also steatite of commercial value on the island.

Madera.

The copper belt which extends through this county in a northwesterly direction from its southern borders is presumably on the same belt as the copper mines in Fresno county. The belt is found among the low hills three miles west of Raymond station, skirting along the east side of the plains of the San Joaquin valley, through the old camp at Buchanan and into Mariposa county, where it rises on the slopes of Green mountain. The formation is mostly mica schist, and the ore deposits occur as impregnations near the surface. Carbonates and oxides are found, which in depth become sulphide (chalcopyrite) with iron sulphide. Copper is also found in the North Fork district near the head of the San Joaquin river.

Mono.

Inyo *Register*: The Lee Bros. of Dove Springs, Kern county, made a discovery in Huntoon valley, there being nine ledges of an average width of 11 to 28 inches, striking northeast and southwest, dipping southeast 70°. The ledges stand one above another, outcropping 6 or 8 feet at many points. The discoverers are now working the second ledge where it dips 30°. They have sacked up twenty tons of rock. In the drift below large masses of porphyry and iron quartz are mixed with slate and volcanic debris. The ledges crop out for 600 feet southwest, up to apex of hill, and carry pay that distance. On the east end they run into the porphyry, but the lower three pass it and continue southeast to the desert, being there covered. Some of the ore is rich and will go $10,000 to $15,000 a ton. Much of the gold is coarse. It is the biggest thing found on the east side since Bodie.

Nevada.

Grass Valley *Union*: The ledge at the Central shaft, near Grass Valley, has been located and is from 1 foot to 1⅔ feet wide. The ledge was cut in the bottom of the shaft at a vertical depth of 800 feet. There are twenty men working at the Central. An engine is being put on the New York Hill to help handle the water in the Central.——It is reported that Dr. Pusheck took $30,000 from the Pierce quartz claim, near You Bet station, the last year. He is adding ten stamps, fifteen men being employed.——At the California mine, near Washington, Supt. D. Harmon, by running a tunnel 2000 feet in length, cut the vein 800 feet deep. Twenty stamps have been dropping day and night for two years. In the tunnel there is a hoist, with which a shaft has been sunk 100 feet.

Placer.

(Special Correspondence).—L. D. Butt, on his Pennsylvania claim, has struck fine ore, running $20 to $50 in gold per ton and more in sulphurets. Messrs. Bruner & Fitch are improving their tramway preparatory to shipping a carload of ore daily to Selby.

Cisco, Aug. 21st, '99.

Colfax *Sentinel*: The owners of the Bellevue mine, near Auburn, have incorporated under the name of the Bellevue Con. G. M. Co. Stock to the amount of 100,000 shares, of the par value of $1 per share, has been issued. The company has secured a new bond on the Bullion Nos. 1 and 2 and the Smith Extension, making 5000 feet on the ledge. The main working shaft will be sunk on the Bullion. Compressed air will be used to run machine drills in sinking the shaft. A 10-stamp mill will be built; but five stamps will be put in place on the start. C. A. Reed of Ophir will be Supt. The cleanup of a crushing of 110 tons before the incorporation amounted to $2400. The total output of the mine since prospecting commenced has been $29,000.——The Jupiter gravel mine, near Iowa Hill, is said to have very rich gravel. A cleanup recently of fifteen cars of gravel containing a large amount of waste rock returned fifteen ounces in gold.

Riverside.

Several veins of white foliated talc have been discovered and opened to a limited extent three miles southwest of Winchester.

Miller, Norton, Case & Frey will develop the mines owned by them twenty-eight miles southeast of Winchester. The ore assays well. There is a large body of it, mainly free-milling. Wood is growing on the section of land owned by the company and a good stream of water runs down the canyon close to the mines.

San Bernardino *Sun*: In the Virginia Dale district the Ferguson brothers have been crushing White Star rock in their 5-stamp mill. The ores of this district are quartz and in normal condition contain sulphides of iron, lead, zinc and copper. The surface ores are oxidized, consisting of quartz with considerable limonite and occasionally copper carbonate. The ores usually amalgamate when carefully handled to about 60% of their assay value, the remainder being obtained by treatment by the cyanide process. There are also some rich chloride silver ores in the district.

San Bernardino.

The Providence mountains, north of Fenner Station, were at one time the scene of active mining operations when the Bonanza King was the leading producer of the district, being a silver mine. In more recent years, however, a number of small but very rich gold veins have been discovered at various points in the range and near it, and this fact leads to the belief that more thorough research may result in the discovery of valuable gold mines. The rocks of the range include limestone, quartzite and schistose rocks (metamorphics) and numerous eruptive dykes.

San Diego.

The salary of the receiver of the Golden Cross mine has been cut from $1000 to $250 per month.

The lithia mine, near Pala, is the subject of present litigation.

The Gold King mill and millsite, Julian, has been sold by F. Ganahl to N. D. Jones, for $5000.

There are in this county some remnants of ancient gravel channels which are gold-bearing, that near Ballena postoffice being a noted instance. The "wash" of this channel system has attracted the attention of several geologists, as it is composed largely of material entirely foreign to the neighborhood, consisting of fragments of quartz porphyry, rhyolite and other acid eruptives. There are no such rocks anywhere known between the Cuyamaca range and the Pacific, and the reasonable conclusion is that they were derived from some locality beyond the mountains in the Colorado desert. Some of the gulches which head into the gravel deposits have been worked by Mexicans for the gold contained, but, so far as known, never yielded more than a nominal sum.

San Diego *Union*: G. S. Andrews has taken a three years' lease on a large tract of land along the coast at Del Mar and will commence boring for oil.

D. Clark, who has had a bond on the Dewey mine, in Grapevine district, near the Warner ranch, has given up his option and discontinued work. The price named was $200,000, which Clark considers too high. Since he took the bond two months ago, Mr. Clark has expended $4000 in development, sinking the shaft from 60 to 100 feet and crosscutting the pay shoot at the bottom, besides drifting a long distance.

Santa Barbara.

One-half of the interest of the Dorothy oil claim, on the beach near Santa Barbara, belonging to the Castle Rock M. Co., has been deeded to J. H. Lundberg of Sacramento for $1000. Their claims, which extend from Castle Rock to the light, a distance of three miles, have not yet been prospected.

G. Wucherer has discovered a gold vein in the mountains back of El Montecito.

Shasta.

The Electric Iron & Steel Manufacturing Co. has incorporated under the laws of Arizona to develop deposits of iron ore on the north bank of Pit river, north of the mouth of the McCloud river. S. G. Smyth, San Francisco, is the Sec'y.

Sierra.

C. B. Wingate, Mgr. Thistle Shaft property, is boring a series of experimental holes on the channel. One hole is down about 500 feet and another between 300 and 400. The result of these borings has not been made public as yet.

The mill at the Triple Pocket mine continues to run, but Supt. Copeland reports that the water is getting short.

C. C. Weisenberger is at the Plumbago mine, two and one-half miles south of Alleghany City, where he will erect a sawmill and a 20-stamp mill on the river below the mine. The sawmill will be completed first to

furnish lumber for other buildings. Ore from the lower tunnel will be crushed. A tramway 1500 feet in length will be built. Mr. Mather is Supt.

The Philadelphus M. Co. has been incorporated by W. W. Treat, W. L. Ducey, G. R. and L. F. Tuttle and P. S. Keefer of San Francisco. This company owns and will operate the Mammoth Springs mine near Forest.

Siskiyou.

N. Cameron, who has recently visited the Little Tiger mine, reports over 1100 feet in tunneling and drifting has been done. The veins recently found are fissures. With the new claims acquired the company owns 110 acres.

Yreka *Journal*: The Gold Star M. Co., working the old Spencer mine on Humbug, has levied an assessment, which is to raise funds to put up a mill. Since reaching the old works with the lower tunnel, good prospects have been found.——The Greenhorn Blue Gravel mine continues to pay on the school house ground, and a new shaft may be sunk to further develop the southern portion of this mine. The reported yield last month was $5000 over expenses.——The Siskiyou M. Co., owner of the Mabel quartz mine, between Oak Bar and Scott Bar, and several claims on McKinney creek, has an engine and boiler, and has ordered a quartz mill from San Francisco.

Trinity.

(Special Correspondence). — A. Miller of Washington, D. C., has bonded the Boulder mine.

The Golden Jubilee mine made a good clean-up last month. In addition to the mill, they have a two-ton cyanide plant and are also shipping ore.

The McDonald Bros. have let a contract to furnish 300,000 feet of lumber to build flumes and for other improvements on the Lykes placer. Night operations will be conducted by electric light.

G. L. Carr is shipping gold ore said to run $300 per sack from the Yellow Rose of Texas on Union creek.

Mr. Hunter has discovered a rich vein on Union creek, 3 feet wide.

Bruner & Cooper are building a cyanide plant on Coffee creek.

P. A. Wagner & Son are running their 12-stamp mill with good results. They are putting in an electrical process to work sulphide ore on the 200 level of the Wagner mine.

The Misses Ryder, owners of a half interest in the Yellow Rose of Texas, have bonded the north extension of that mine.

G. G. Culbertson has four men working on a ledge 3 feet wide near the Wagner mine.

Supt. Walden of the Black Eagle mines reports having crosscut the ledge 70 feet, the ore averaging $6 per ton.

A number of copper prospects are being opened around Carrville.

Strode Bros. have closed down the Oro Grande mine for the season.

Trinity Center, Aug. 18th, '99.

Redding *Searchlight*: The Boulders M. Co. has been organized by G. L. Carr of Carrville. Three of the members of the company are prominent railroad officials of the East. The property to be worked is the Boulders, twelve miles west of Castella. The purchase price was $75,000. The Boulders consists of nine claims, comprising 180 acres. Its ore consists of boulders of various sizes scattered over the property. Three years ago the Boulders was purchased by Mr. Carr, who has since run three tunnels aggregating 1500 feet.

Redding *Free Press*: Development work on the Keating mine, in Hardscrable district, is progressing satisfactorily. Work in the upper tunnel has been suspended owing to the large flow of water, causing dangerous sides. A new tunnel, 50 feet below the old one, is being run, which will tap the ledge 500 feet below the surface.——Work is progressing at the Burgess mine, on Hickey creek, a tributary to Coffee. Last spring a 100-foot tunnel, crosscutting the ledge, was run, which tapped it 60 feet below the surface. The width of the ledge is 16 feet; the ore assays $10 to the ton. It is the intention of the company to put up a mill.——Pitts & Manning of Oro Fino have a good prospect on Coffee creek. They are getting out ore which runs $16.——At the Nash mine the big race is finished. It will connect the tunnel running through the mountain with the shooter at the junction of Union and Coffee creeks, 500 yards above the mine. Preparations to build a new flume and to open up above the shooter are being made.——A power drill will be put in True, Norton & Co.'s Morning Star mine.

Tuolumne.

The superintendent of the Boston & Tuolumne G. M. Co. reports that the Longfellow mine, which adjoins the Tuolumne, has struck a shoot of ore on the 300-foot level, some of which shows $7000 a ton. The ore is being sacked and shipped. At their mill, after a week's run, they cleaned up $12,800.

Sonora *Union-Democrat*: The Leechman Prospecting Co., Ltd., has sued Sheriff Price for $10,000 damages, together with costs and $5000 additional for rents and being deprived of the possession and profits which might come from the Keltz mine, ten miles north of Soulsbyville. Sheriff Price seized the property, together with the mill and other improvements, at a time when it was under attachment.

Sonora *Union-Democrat*: At the Black Oak sinking is in progress in the main shaft, now down 850 feet. The greater portion of the ore at present comes from the north drift of the 800, though much milling quartz is sent out from levels above. A new two-compartment shaft has been started on the Live Oak, an extension of the Black Oak, south, which is down 10 feet. As in the case of the main shaft, the vein is being followed.——The Longfellow mine, near Groveland, continues rich. Preparations are also being made to sink the main shaft, now down 350 feet, 600 feet deeper.——It is reported that miners in the main shaft of the Providence mine, near Carters, found a body of rich ore last Monday. It is said that the rock is heavily impregnated with gold.——The Bonanza at Sonora has closed down temporarily owing to a lack of water to run the mill and compressors. Twenty men are out of employment.——At the Goldwin the winze from the tunnel has been driven to a depth of 110 feet, with farther sinking going on, and the bottom showing a 3-foot ledge of quartz. The winze is now a working shaft, as from it an upraise was driven through the old stopes to the surface, 95 feet. W. H. McClintock is Supt.

COLORADO.

CLEAR CREEK COUNTY.

Denver *Post*: Mining is on the increase in the upper end of this county, several old properties having recently been started up. The Progressive Eight M. Co. has filed articles of incorporation for 500,000 shares, the company being Pueblo men, and their property on Griffith mountain, above the Griffith mine.—— On the Pueblo lode is a 250-foot tunnel from which ore is being taken from an 8-inch streak. The ore runs in copper, lead and gold.——McLaughlin & Co. have struck the junction of the Emma and Rogers lodes at a distance of 2500 feet in the Mathews tunnel on Democrat mountain and are taking out ore that will run from 300 to 700 ounces silver per ton.——While mining for zinc on the Burleigh tunnel, the Humphrey Zinc Co. struck ore running 900 ounces per ton in silver.——The Maxwell concentrator, now being built at the Mendota mine, will treat the entire dump.——The reported strike on Chicago creek, three miles east of Georgetown, is now said to amount to nothing. A number of men from Georgetown went over to investigate the rumor, but could find nothing of the reported strike.

Silver Plume *Standard*: A gasoline engine will be put in at the Illinois tunnel of the Pelican property.

DOLORES COUNTY.

Rico *Sun*: P. T. Nixon and S. E. Custis are shipping ore to Durango from the Montezuma vein, where they are leasing.——An assay made from ore taken out of the Hiawatha vein of the Enterprise group recently returned 3900 ounces silver and 10 ounces gold per ton.

GILPIN COUNTY.

The Pratte G. M. Co. of West Virginia have bought some of the best claims in the Yankee Hill district, besides taking a lease and bond on others. The company have decided to put up a mill and also an air compressor plant. The mill is to be a combination concentrating and amalgamating mill. When completed it will cost in the neighborhood of $50,000. The company will extend the '94 tunnel to cut the Stonewall, Texas, Whale, Storm and Howell claims, all of which are large veins and show good bodies of milling ore. The Stonewall is equipped with a 60 H. P. boiler and engine. The vein will be tapped 200 feet deeper than the present bottom of the shaft. The Texas has been developed by a shaft 160 feet deep and is equipped with machinery. A continuous body of ore has been opened up. The Whale shows a large vein of low-grade ore and has a shaft 60 feet. A sawmill has been built at the mouth of the tunnel to cut timbers for mine work, and a head house 36x40 feet has been built at the mouth of the tunnel, in which will be placed the air compressor plant. An assay office and several dwellings have been erected.

GUNNISON COUNTY.

Denver *Post*: The Crystal River M. Co., recently freed of litigation, is owner of the Black Queen, Fargo and other silver and copper mines on Sheep mountain, and has sold out to a New York syndicate for $500,000. The Black Queen has been producing for years, the ore running 100 to 110 ounces of silver to the ton, with copper values, though the operators have only recently discovered this. The Fargo, adjoining the Black Queen and on the same contact, runs $42 a ton in lead and copper. Twelve other claims belong to the group.

Pitkin *Miner*: J. J. Huddart of Denver, lessee of the Mono mill, has leased the Jersey Blue mill, in the Gold Brick district, of R. R. Williams. The Jersey Blue is a 10-stamp mill and the lessee will put in six 12-ton tanks. A combination process similar to cyanide will be used at both mills.

LAKE COUNTY.

C. E. Potter, Sec'y Fairmount Zinc Co. of Fairmount, Indiana, is inquiring into conditions at Leadville as to character and quantity of zinc ores available, with a view to the establishment of a zinc smelter at the mines.

The Coronado shaft on East Seventh street, Leadville, is shipping five loads of iron daily to the Arkansas Valley Smelter. The Bon Air workings have been put in shape, new ground is being opened and the mine is on a shipping basis. The Yankee lease of the Orion is also sending ore to the Arkansas Valley Smelter.

The Little Johnny, it is reported, last year produced 100,000 tons of ore. It employs 500 men. The ore bodies carry chiefly gold and copper. The M. A. W. Co. is putting down a shaft to a depth of 1500 feet. The down-town mines are all working again after $100,000 had been expended in unwatering them.

J. McAllister is shipping from the Mike and Starr. Before closing down on account of the smelter shutdown, Mr. McAllister was opening a rich ore body. He will ship from the iron-sulphide body, which has already been proven for a thickness of over 40 feet.

F. Schmidt, having purchased the S. Small mill site, has started up the old Hibschle shaft on that territory and is working at the 300 level.

In the Evans gulch section a new three-compartment shaft is to be started by the Resurrection G. M. Co. between the Dollie B and Diamond shafts. This company owns 364 acres. Its ore body is tapped by the New Years and Little Ellen inclines and the 950-foot shaft on the Kokomo claim. This shaft will open new territory and should catch the extension of the ore channel from the Dollie B.

Leadville *Miner*: The Theodolite group, in Lackawanna gulch, is owned by J. T. Peters and T. S. Wood. A. Hartwick, the lessee, has a six-ton shipment now in Leadville which, judging from assays, will mill fourteen ounces in gold. S. Yankee and associates have found a vein above timber line in Echo canyon, near the Thomas Anthony mine. It can be traced 3000 feet and the ore will average $20 per ton.

MINERAL COUNTY.

At Creede the Commodore has commenced shipment of three cars per day to the Bimetallic at Leadville, and other properties have increased their daily output.

The Last Chance, which has been closed for two months, has put a number of men at work and is getting out ore.

The Ridge has increased its working force in the past three weeks and is working nearly full shifts in all portions of the mill and mine. Large quantities of zinc and lead concentrates have been shipped from this property in the past few months, much of this going to Weir, Kan. Large quantities of this high-grade blend are still in the bunkers.

Ore shipments from Creede during the week aggregated 1600 tons. Among the mines that will resume when notice is received from the Pueblo smelting plants are the Amethyst, Last Chance, Bachelor No. 2 and Commodore. With these properties in working condition, the output of the camp is predicted at about 10,000 tons weekly. Within two weeks, shipments are expected to reach 5000 tons.

MONTROSE COUNTY.

G. Kimball has sold his uranium property in the La Sals to French capitalists.

The La Sal Copper M. Co. have closed down their mines and are putting in a reduction plant for the treatment of the low-grade ores of the Angell and Red Chief mines.

OURAY COUNTY.

Ouray *Herald*: A rich vein of ore has been cut in the second level of the Newsboy. For several months Shue, Du Praw and Stalford have been working this portion of the Newsboy under lease. The Newsboy adjoins the Slide property and is entered through the tunnel of that mine. They have extended the Slide tunnel 120 feet into the Newsboy property, where the strike was made. The vein cut was found in quartzite and is 30 inches wide.——D. Wood is equipping the Black Lightning in Poughkeepsie gulch, upon which he has a bond and lease.

SAN JUAN COUNTY.

Silverton *Standard*: The San Juan Mining Association have decided to work their mines with eight-hour shifts, and the Iowa, Tiger, Sunnyside, Gold King and Sampson are at work. During the shutdown repairs and cleaning up have been going on.

SAN MIGUEL COUNTY.

Ophir *Mail*: The Mountain Key has been put in shape and is working again. The copper vein uncovered a few weeks ago is being opened and a carload is to be shipped.——The Butterfly mine is working forty men on the eight-hour system.

TELLER COUNTY.

A strike of rich ore is reported in the Doctor mine on Raven hill, discovered by crosscutting, which was done by leasers, the owners having neglected this important matter and leasing the mine when the amount of ore in sight was nil.

Fire destroyed the business portion of the city of Victor on the 21st, causing a loss estimated at $2,500,000. The town had been built in the early days of the district, and was of pine timber, which burned rapidly. Efforts were made to stop the progress of the flames by blowing up buildings in their path with dynamite, and all afternoon the hills roared with the explosions, but to no effect. All the buildings burned are a total loss, with practically all their contents, for the flames were so rapid that nothing could be saved. The scenes of the great Cripple Creek conflagration were duplicated. A special train was placed at the command of Victor by the Florence & Cripple Creek Railroad, and three companies of firemen, with apparatus, rushed over and worked all the afternoon in a vain endeavor to stay the march of the flames. The first house was built in Victor in October, 1893. In July of the following year the city was incorporated, and six years later it contained 12,000 people. The total number of buildings destroyed is estimated at 800. Fourteen blocks, comprising almost the entire business section of the town, are in ashes. Insurance, from $400,000 to $800,000. The most valuable buildings destroyed were the Gold Coin mine shaft houses, the loss on which is $100,000. Victor is the metropolis of the southern end of the Cripple Creek district and will be quickly rebuilt in more substantial manner than before.

Cripple Creek *Times*: In a crosscut from the Blickenstaff shaft on the Specimen, run at 275 feet to cut the Lafayette vein, 10 inches of ore was broken into in what is supposed to be a new vein. Assays run 102 ounces.——In the Pinto of the Free Coinage Co. what is said to be a new vein has been cut. Pay is 2 feet wide, and some of the rock assays $5 a pound.——Blickenstaff and associates, on the Lucky Guss, have stopped work in the shaft and started a crosscut for the rich shoot that comes into the property from the Lafayette ground. The average grade of the rock they are breaking is five ounces.——Mgr. Davenport has received returns from two lots of ore. One shipment of eleven tons was settled for at 32.95 ounces, and the other lot of seventy-three tons brought 14 ounces per ton.——It is stated that the Isabella is again in rich ore, and that the rich shoot was cut in an upraise from the tenth level. It is reported that the Isabella Co. intend to resume sinking the main working shaft, now 730 feet deep.—— The Modoc has ready for shipment two carloads of ore that will average 200 ounces per ton, and ten cars of rock from five to seven ounces. This ore comes from the east vein, which has been opened in all the levels of the mine down to 700. This fissure is supposed to be the extension of the Lafayette vein.

IDAHO.

BOISE COUNTY.

The town of Placerville was totally destroyed by fire on the night of Aug. 17, with a loss of $70,000.

Idaho City *World*: Fulk, Whaley and Blois have located four quartz claims twelve miles below Silver Mountain on the north fork of Boise river. Two of the claims are on a ledge 12 feet wide and are 600 feet apart. The ore assayed 2.7% copper, $12 in gold and from five to six ounces silver. The ledges crop in places for 4000 feet and show copper for that distance.

OWYHEE COUNTY.

Silver City *Avalanche*: The Cumberland mine on War Eagle mountain was recently sold to a Montreal syndicate. It was owned by I. & T. Shaw and has been developed while under bond to Sonnemann & Branscombe of Spokane. The resident Mgr. is Francis Jenkins. Work is confined to the 200 and 300 levels, where they are driving north and south, opening new stoping ground. A winze is being sunk at the 200 level to connect with the 300 level, in which they have encountered 1 foot of ore, coming in from the hanging wall, rich in gold. Orders have been placed with Fraser & Chalmers of Chicago for a 10-stamp combination mill, a 10-drill air compressor and a steam hoist to work to 1500 feet.

SHOSHONE COUNTY.

Spokesman-Review: A great deal of work is being done at Buffalo now that the weather is good. On the Dewey they are crosscutting. This lead lies along a small water course, and the footwall being soft has been worn away by errosion, and exposed the quartz for a distance of 1000 feet to a depth of from 1 to 6 feet. The crosscuts show the vein to be 6 to 10 feet in width. Just above the Dewey on the same lead is the Sacramento, which lies higher than the bed of the stream, and the owners are ground sluicing to uncover the lead. Above this claim on the Grubstake the same thing is being done. Men are at work on the St. Paul, but have abandoned the first crosscut tunnel, and are opening the lead in another place. A shoot in the vein 2½ feet wide assays $200 to the ton, and free gold is visible. Norman & Cameron are at work on the Monte Cristo, with four men. Owing to water in the shaft they have gone down the hill to run a crosscut and will tap the lead. They also have men on the Fortune. It is reported that Clark & Sweeny have obtained control in the Big Buffalo. The snow is practically all gone from the camp. Only drifts remain in sheltered places. The nights are cool, and frequent frosts appear. On the morning of August 2d ice was formed on still water one-eighth of an inch thick.

MICHIGAN.

HOUGHTON COUNTY.

At the annual meeting of the Calumet & Hecla M. Co. the following directors were elected: A. Agassiz, F. W. Hunnewell, Q. A. Shaw, Jr., J. N. Wright and F. L. Higginson, the latter succeeding H. L. Higginson. With the opening of shafts Nos. 16 and 17, on the Osceola amygdaloid, the Calumet & Hecla Co. will have five shafts on the line of the amygdaloid. Of the shafts now connected, it has a total length of nearly 5000 feet on the lode. When 16 and 17 are opened, the company will have a total length of 11,000 feet on the lode. It will cost the company $1,000,000 to complete shafts 13, 14 and 15, with hoisting plants, which will be done by the fall of 1901. Pres. Agassiz says the showing at the Red Jacket shaft is the best in the mine, although it is the deepest part of the mine.

In Tamarack Shaft No. 3 thirty-five drills are running and sending out more ore than any other shaft.

It is reported that at the Franklin 400 to 450 tons of ore are stamped per head daily.

MISSOURI.

JASPER COUNTY.

The total zinc production last week was 11,500,600 pounds; total lead production, 1,028,000, both having a total value of $356,668.

Joplin *Herald*: On the Chitwood Hollow claim of the United Zinc & Lead Co. eleven new shafts are in process of sinking. The Chitwood Hollow tract has been more thoroughly prospected with a drill than any other land known. The drill in one of Adam Scott's holes went into 40 feet of good ore at 168 feet. Of the Houk shafts the one now in use was sunk on one of the poorest drill holes, and it has been a big producer from the beginning. ——The Conqueror mill is producing thirty tons weekly.

MONTANA.

JEFFERSON COUNTY.

Butte *Inter-Mountain*: E. R. Holden & Co. of New York have secured control of the Hope mine at Basin. It is proposed to build a new concentrator and start up the mine, which has been closed down for some time on account of a fire which destroyed the shaft and killed several men. The mine has yielded $700,000. The Basin G. & C. Co. is the name of the new company, organized under Montana laws, with R. B. Smith, Governor of Montana, as president. The company is capitalized at $2,500,000, with 500,000 shares. Besides the Hope the new company owns fourteen patented claims in Basin. The main shaft on the Hope is down 600 feet and it is alleged that there are several thousand tons of ore in sight.

NEVADA.

The pumping operations at the C. & C. shaft, Comstock lode, continue without interruption and the water is slowly going down. The slow progress indicates that large

excavations are being drained. These passed, better headway may be anticipated. Manager Ross has sent the following telegram:

VIRGINIA, NEV., Aug. 24, 1899.

To Aug. Waterman, Secretary Comstock Pumping Association, San Francisco: — At 6:30 this morning the water was 31 feet 6 inches below the 1050-foot level. No. 1 elevator has been running continuously.

WHITE PINE COUNTY.

White Pine *News*: The Chainman mill has been rearranged and is at work cyaniding the tailings which have accumulated. Besides its cyaniding plant, the company has a complete 10-stamp amalgamating and concentrating mill. There is ore in the mine blocked out to keep the mill running two years.

EUREKA COUNTY.

Eureka *Sentinel*: G. L. Bemis and R. A. Campbell of Bingham, Utah, have been visiting the Ruby Hill and Adams Hill mines. Mr. Bemis also made a trip, in company with H. Kind and T. Dixon, to the Dimick mines at Tybo. The object of the examinations is to ascertain the character of the ores and the possibility of concentrating and cyaniding them, should they be found to be in sufficient quantity and value to justify the establishment of a plant for the purpose.

LINCOLN COUNTY.

The cyanide plant in El Dorado canyon is running successfully on a large dump of tailings, and it is stated that two new quartz mills are to be erected in that district.

NEW MEXICO.

GRANT COUNTY.

A. W. Tennant, representing the Hanover Copper Co., has bought from J. H. Bragaw, J. A. Potter and A. Johnson the fourteen claims of the Modoc group for $140,000, of which $10,000 was paid in cash.

The Pinos Altos G. M. Co. is pushing work on the reservoirs and dams.

At the Gillett shaft the new shaft house is being framed. A 100-ton concentrator will be built at the Gillett shaft. B. B. Thayer is Mgr.

OREGON.

GRANT COUNTY.

The Great Northern M. Co., near Canyon City, has started up its new mill. The plant has a capacity of twenty tons daily. The milling ores show an average of $15 per ton in gold, while pockets are encountered. These latter have yielded over $5000 in the past few months, one pot recently turning out $1500.

LANE COUNTY.

(Special Correspondence). — The Bohemia mining district is in the Calapooia mountains, a spur on the west side of the Cascades, thirty-five miles east from Cottage Grove and forty miles from Eugene, the county seat of Lane county. It is at the upper end of the Willamette valley. The district is at 5000 to 7000 feet above sea level and covers an area of forty square miles. It is in line with the mineral belt which extends through northern California, Oregon, Washington and into British Columbia. The formation is of volcanic origin with andesite and porphyry. The tops of some of the peaks are covered with decomposed bleached lava. There are two trends of fissure veins, one of which runs parallel with the Cascade range and the other runs east 20° south. A few properties have been worked since '92 and have paid from the grass roots. One is down 250 feet, another 350 feet and still another 450 feet. All have shown increase in size and retain their values with depth.

The Musick started with five stamps of 750 pounds each and a 10-foot prospect hole. In thirty-six months run it paid over $100,000 from free gold and $30,000 from concentrates. J. W. Cook, the main owner and manager of the property, certifies to this statement. This year ten stamps are being operated, a new mill having been recently put in.

Among other properties that have been operated are the Noonday with twenty stamps; Fairview, five stamps; Johnson, two stamps; Champion, ten stamps. The returns from these properties are reported satisfactory.

The many prospects upon which development has been done by sinking or tunneling have shown improvement, and some of the prospects have by assay shown rich ore bodies at a depth of 50 feet. The surface ore of the Musick mine averaged $5 to $20 per ton, the vein being 18 inches wide. At a depth of 75 feet the best of the ore, 4 feet wide, assayed $40 to $200 per ton, and at 125 feet the vein was 8 feet wide.

The surface ore of the Helena ran from 50 cents to $2.65 gold per ton. At 30 feet depth by a drift 75 feet on the ledge the ore assayed $25 to $30,000 gold to the ton, the pay streak being 6 feet wide with 1 foot showing free gold; and the tunnel, when continued 90 feet farther, showed free gold the entire distance.

Eugene, Aug. 18th, '99.

SOUTH DAKOTA.

There are several belts or zones of copper-bearing ores in the Black Hills. The ore deposits occur at intervals along the line of large reefs of quartzite which extend for many miles in a northwest and southeast direction. When the shoots of ore occur, the quartzite is found jasperized and the croppings are often over 100 feet in width. The slate rocks accompanying are often found to contain copper in payable quantity, but in depth the ore is usually found confined to one wall of the main quartzite belt. The surface ores are carbonates (malachite and azurite) and black and red oxides. In depth these give place to sulphides of iron and copper. In places the surface deposits are very rich, and copper can readily be smelted from the ores in a cupola.

LAWRENCE COUNTY.

It is reported at Deadwood that the Hearst interest (one-third) of the Homestake consolidation is to be sold next month in London. The Homestake was originally incorporated in '77 for $10,000,000. Several years later it absorbed adjoining property and the capitalization was increased to $12,500,000. Recently the Deadwood-Terra and the Highland Companies' holdings, together with the Black Hills & Fort Pierre Railroad and the Black Hills Canal & Water Co., have been consolidated with the Homestake with a capitalization of $21,000,000. The entire interests of this concern are under the direction of Mr. T. J. Grier, who has been identified with the company since '78, and who succeeded S. McMaster as Gen. Supt. at the time of his death.

UTAH.

The incorporated mines of Utah during the first half of August paid $147,000 in dividends.

Salt Lake *Mining Review*: During August numerous important strikes have been reported. Among them are the following: In the Cedar Valley in Peepstone district, Bunker Hill mine at Stockton, Woodlawn mine in Big Cottonwood, Chicago mine at Bingham, Dalton & Lark mine at Bingham, Star Con. mine in Tintic district, Mammoth mine in Tintic district, Tetro mine in Tintic district, Utonia mine in Death canyon, Massachusetts mine at Park City, New State mine at Little Cottonwood, Tesora mine at Tintic.

JUAB COUNTY.

Salt Lake *Tribune*: Diamond, in Tintic district, will have a custom plant for milling its ores before winter. The movement is headed by Roi Bemis.——The Bowers is jigging its milling ores, and the management of the Shoebridge will erect a plant as soon as the water level is reached, and the Tesora will follow. Mr. Bemis' plan is to relieve these companies and others by whom jigging plants are being projected of the outlay that will be entailed by establishing a custom plant at a central portion of the camp, and if he can close his contracts for the ores in question will place his orders for machinery before the end of the month.

SALT LAKE COUNTY.

New strikes in hitherto unexplored ground are of frequent occurrence in the property of the United States M. Co. at Bingham. The recent strike below the Confab stope has developed into 26 feet of ore. A discovery has been made in Old Telegraph ground, 8000 feet east of the strike in the Confab shoot, where Supt. Turner has uncovered 13 feet of ore that shows high-grade copper, eleven ounces silver and $1.60 gold per ton.

New work in the old Bowden stope, in Old Telegraph ground, from which the highest grade copper ore ever shipped out of Bingham was taken, has also shown new ore bodies, which assay 13% copper, 11.8 ounces silver and $1.20 gold per ton, with 31.2% iron and 8% silica.

Recent work, directed by Mr. Neill, has resulted in opening up the old Lion's Den stope, from which $960,000 was taken.

TOOELE COUNTY.

The Golden Gate mill, at Mercur, which for a long time has been shipping auro-cyanides, will again commence the reduction of the precipitate at the works. Supt. Jackling has been perfecting the methods, with such results that it has been decided to start up the plant again. The output has been increasing for some time and the value of it is estimated between $150,000 and $200,000 per month.

WASHINGTON.

STEVENS COUNTY.

In the Princess Maud, at Republic, the winze is down 20 feet, with 3 feet of quartz in the bottom. A foot of it is rich, the rest carries good values. There is a large percentage of silver in the ore. Two assays gave $267.22 and $229.49.

The Georgie Reed group is south of Republic, at the forks of the San Poil. It is under development by a Spokane company. T. E. Dexter is Supt. The crosscut tunnel running to tap the Georgie Reed vein has cut a blind lead. The vein was opened in diorite and showed quartz of greater hardness than that in the main vein. Mr. Dexter reported an assay across the face of the tunnel which had not crossed the vein, running $21 gold and $17 silver.

Spokesman-Review: The drifts on the 150-foot level of the Tom Thumb are showing up a fine body of high-grade ore.——Supt. Coy reports that good progress is being made on the Golden Lily shaft.——R. L. Barbee and associates have taken a contract to sink a 50-foot shaft on the Vulcan No. 1. It is down 25 feet. The ledge is 8 feet wide. There is one fine stratum of ore next to the hanging wall. Near the surface the rock assayed $1.89. At the bottom of the shaft the average is $7.80. The property lies 300 feet southwest from the Mountain Lion ground. The claim is owned by G. W. Dickinson and associates of Seattle.

WYOMING.

CARBON COUNTY.

E. H. Haggerty has taken a working bond on the A. Bragg property at Battle Lake for $25,000, with four months' time. A 35-foot shaft has been sunk through copper-stained quartzite and a short crosscut run to cut the lead.

A company has been organized for the development of Grand Encampment mines. The incorporators are N. H. Withee and E. Peck, capitalists of La Crosse, Wis. The company has bought a group of four claims, six miles from Grand Encampment. The company has let a contract for a shaft to be sunk 100 feet on a lead 12 inches wide at the surface which assays 9½% copper and $2.10 gold.

FOREIGN.

AUSTRALIA.

Melbourne *Standard*: The Mount Gunson copper field is ninety miles northwest of Port Augusta. It is reported that the ore covers acres of ground and the total quantity of ore in sight is estimated at 200,000 tons, allowing a depth of 6 feet on one claim. No lode has been found or determined. In Mr. Brennan's mine, known as the C. Mavis B, the workings are a large open cut 18 feet deep, surrounded on all sides by copper ore of an average of 9%. Several bags of rich copper ore from the Moortonton Estate, Millbrook, the property of J. Tippett, have been forwarded to Adelaide. The samples comprise grey and black ore, through which malleable copper is disseminated, red oxide and green and blue carbonate of copper. There are five distinct lodes on the estate.

BRITISH COLUMBIA.

(Special Atlin Correspondence).—The Pine creek discovery of gold, reported at Lake Bennett in July, 1898, was known to prospectors about six years previously, but the prospects were not such as to induce them to bring in supplies at that time. But the rush of '98 boomed it as it never could have boomed on merit. It is a region of low, rounded mountains, partly of eruptive origin.

The formation is irregular, consisting of diorite, rhyolite, serpentine, granite and schist, with inclusions of quartzite, marble, slate, porphyry and other rocks. Many of the high summits are covered with fragmentary rocks.

Erosion, to which the placer mines owe their existence, appears to have been limited to local glacial action, with little evidence of pre-glacial streams.

The glacial moraines on the sides of the mountains indicate that the ice had a depth on Pine creek of 1000 feet, with the source five to thirty miles distant; yet the cutting and filling effect has been less than one would expect. Since the glacial action ceased, water has cut out canyons.

As to the character and source of the gold and the value of the mines, the gold will assay $17 to $18 per ounce, but contains much quartz, reducing the average value to about $16; and wherever the diggings pay wages the gold is coarse, two-bit colors being common and ounce nuggets not rare.

A little fine gold may be found anywhere in the glacial drift, but it is very fine and the total amount small, so it can not be considered a source of pay, although it has led to the staking and recording of several thousand claims, of which few will ever yield net profits, and not one in twenty will return the recording fees.

The dirt that will pay for working by pick and shovel method is, so far as known, confined to two miles of Pine creek, one mile of Wright creek, one mile of Spruce creek, and fifty claims on Boulder, Birch and McKee creeks (Willow creek is a branch of Pine), and within these limits are many claims that will not pay wages, as the bedrock is very irregular and the pay spotted. There is a total of 100 claims, each 100 feet wide, that will, if worked to advantage, yield a profit, though there is not what an old-timer would call a rich mine in the whole district, six ounces per day to the man for shoveling on bedrock being the best shown to date.

There were 6000 to 7000 men in the district when navigation opened this spring.

The gold found in the pay dirt appears to have been derived from the cutting down in the locality of the rhyolite and serpentine, which contain seams and pockets of gold-bearing material. Recently a kidney of quartz and porphyry, showing "pinhead" gold, was found below water level on Pine creek by men cutting a drain at the mouth of Willow creek. There are no ancient channels here.

Of quartz mines, forty or more locations have been made, five or six of which possess doubtful value. The remainder are valueless.

The kidney of quartz mentioned is yellow, 18 inches wide, accompanied by a fine-grained yellow and red porphyry. If it were a continuous vein it would make a valuable mine.

Some miles to the northeastward a 30-inch vein of milk-white quartz crops 200 feet. A prospect hole 12 feet deep showed streaks of galena, zinc blende, black sulphurets of silver and flakes of gold telluride; walls dark schist, carrying pyrite.

The sources of gold are in the gulches, or at the base of the mountains, the summits showing nothing of value whatever.

Hydraulic mining has not been successful yet, although parties are reported to have brought in outfits more or less adapted to the circumstances. Very little of the ground is in possession of miners of previous experience, however, and such are not buying any of it.

It is the opinion of competent miners that there is enough of fairly good ground in the district to keep six or eight companies of Chinamen employed for several years—say four miles of channels and eighty or a hundred acres of bench ground in all. The total output of the district to date would be a difficult thing to estimate. PHILIP MINOR.

Pine City, Aug. 7th, '99.

A number of the miners imported from Sudbury to work on the Ymir mine were induced to quit work in consequence of the representations of the local miners' union. These men had signed a contract in Ontario to work for six months at $3 per ten-hour shift. After working a few days, they quit work and demanded their wages. The Ymir Co. refused to pay, in consequence of the breach of contract in which six months' work was contracted for. The men have gone to Nelson to sue J. R. Robertson, the managing director.

A strike of nickel ore is reported from Fort Steele district of East Kootenay. The claim is the Grace Dore and was discovered by Robert Dore, the Wild Horse prospector. The claim is four miles from Fort Steele on Wild Horse creek, near where Brewery creek empties. There are 4 feet of ore, with 1 foot of solid mineral, and assays show values of 12% to 15% nickel.

Mgr. Ward of the Ward M. Co. of Horsefly is getting out $2000 to $3000 daily.

Spokesman-Review: Another find in Summit camp is reported at Grand Forks. Men doing assessment work on the Senator discovered iron in the rock clinging to the roots of an upturned tree. They excavated a pit and at a depth of 2 feet uncovered a rich ledge. On No. 37, an adjoining claim, owned by J. B. Henderson, miners cut an open pit near the boundaries between the two claims and found the same lead. The ledge is 80 feet wide and there is shipping ore mixed with gangue 3 feet from the surface. This is the fourth ledge uncovered on that property.——A strike has been made on the Morrison mine. At the depth of 230 feet a body of 20 feet of solid ore has been encountered, yielding $13 to $33 in gold and some copper.

CANADA.

In northwestern Ontario there are eighteen stamp mills; number of stamps, 257. There are already employed 3082 miners, receiving $1,000,000 a year in wages. The gold production for that section for '99 is estimated at $600,000.

Work is under way, after a cessation of six years, at the silver mines of the Thunder Bay region on the north shore of Lake Superior. Four mines on Silver mountain have produced 800,000 ounces. Concentrates of the lower grades are shipped, valued at $600 to the ton.

NEW ZEALAND.

Melbourne *Standard*: The Waihi Co., during last month, treated 7715 tons for a return of bullion worth £22,444.——The Talisman lately crushed 883 tons of ore for a return of 4100 oz. 11 dwt. of bullion, valued at £3214 3s 6d, a fraction over £3 12s 9½d per ton.——Ore from the Golden Belt mine, Neavesville, was treated recently at the Thames School of Mines experimental plant; 850 lbs. were treated by the cyanide process, which gave an extraction of 75.4%.——A parcel of 800 lbs. from the Venus was treated by pan amalgamation at the Thames School of Mines, and the tailings ground, for a return equal to 79.5% of its value. A portion of the same ore was treated by cyanide in the laboratory for an extraction equal to 91.9% of its value.

THE YUKON.

The British America Corporation of Vancouver, B. C., an English company, will commence development work on a copper mine four miles inland from White Horse rapids. A tram line is to be built from the mine to the river.

Some Recent Additions to the Mineral Collection of the California State Mining Bureau.

Copper ore, chalcopyrite and bornite, carrying gold and silver; Van Anda mine, Texada island, B. C.; J. Arnheim.

Bismuth-gold; 60% gold, 40% bismuth; first occurrence of this mineral noted in California; Coon Hollow mine, near Placerville, El Dorado Co., Cal.; G. E. Kastengren.

Gold quartz, 1200 feet wide and hanging wall rock of same; Picacho district, San Diego Co., Cal.; P. C. Du Bois.

Phosphate rock from Tennessee and from the Gulf of California; T. J. Wrampelmier.

Gold quartz, Francis mine, Mariposa, Cal.; Waggoner & Maddern.

Gold quartz from the new ledge recently found in the Gwin mine, Calaveras Co., Cal.; J. J. Crawford.

Oil sands and petroleum shale from the southern oil fields.

Fossil horse hoof from Sepulveda station, Los Angeles, Co., Cal., and on the same Jay one from 27 feet depth under gravel on Dominion creek, Klondike gold field; E. Landegren.

Copper ores from Marin Co. and Siskiyou Co., Cal., and Butte, Montana.

Native silver, stephanite, corvellite, hubnerite, tetradymite, pyrargyrite, bismuthinite, corundum and other minerals from Montana; F. W. Traphagen.

Corundum in feldspar, margarite and diaspore from a large ledge in Plumas Co., Cal.; J. A. Edman; first noted occurrence of this useful mineral in place in California.

Native copper from the conglomerate at the 3500 level of the Calumet & Hecla mine, Michigan, and auriferous pyrite carrying $200 to $400 gold per ton; R. L. Hornbrook.

Coal briquette, made in Germany from crushed lignite by pressure only, no binding material being used.

Massive talc of good quality, now being marketed; from the "Talc" mine, Ventura Co., Cal.; S. S. Simon.

Fossil bison horn of new species, horse teeth, etc., from the southern oil fields.

And several others.

HENRY S. DURDEN, Curator.

Recently Declared Mining Dividends.

Wolverine M. Co., Michigan, dividend No. 3, $2 per share, which is an advance of 50c per share; payable Oct. 2. Total, $270,000.

Breece M. Co., Colorado, 5 cents per share; payable Sept. 1.

Gold Coin, Cripple Creek, Colo., No. 22, $10,000; Aug. 15.

National Lead Co., quarterly dividend, 1¾% on preferred stock; payable Sept. 15.

Homestake M. Co., Lead City, South Dakota, regular quarterly dividend, 25c and extra 25c per share, $105,000; Aug. 15. This is under the new plan of organization, with 210,000 shares, the former capitalization being $12,500,000, divided into $100 shares.

Mammoth, Utah, 15c per share, $60,000; payable Sept. 1. Total, $1,530,000.

Standard Con., Bodie, Cal., 10c per share; Aug. 24.

Grand Central, Utah, $37,500; Aug. 11.

Swansea, Utah, $5000; Aug. 11.

Silver King, Park City, Utah, $50,000; Aug. 11.

Bullion-Beck, Utah, $10,000; Aug. 20.

Industrial Notes.

—The War Department will soon buy 40,000 horses.

—Las Vegas, N. M., will build municipal water works.

—Pomeroy, Wash., proposes to put $18,000 into an electric plant.

—There is a present demand for labor in every part of the country.

—The region on the west side of Cook Inlet, Alaska, is being prospected for oil.

—Long Beach, Cal., reports a daily catch of 200 sharks, which furnish "cod liver" oil.

—In the Lake Superior iron mines 19,000 men are employed and many more are needed.

—The receipts of the San Francisco post-office for the year ending June 30th, '99, were $1,002,056.

—From London to Dawson in seventeen days is the latest quick time record made by a mining engineer.

—Preliminary surveys are being made for the entrance of the Sierra Valley Railroad into Reno, Nevada.

—Austin Corbin Jr. is credited with having made $1,000,000 since July 1st, '98, in zinc mining at Joplin, Mo.

—A railroad is to be built from Monclova to Mazatlan, Mexico, 1265 kilometers. The cost will be $12,000,000 silver.

—The San Joaquin, Cal., Electric Co. has been sued by the N. Y. Mercantile Trust Co. for overdue interest on its bonds.

—Colorado justly proposes setting aside sufficient state school lands to insure necessary income for the Colorado State school mines.

—An authority estimates that the output of pig iron in the United States in 1899 will be 13,250,000 tons and in 1900 will reach 14,500,000 tons.

—All the mining counties of California show an increase in the 1899 assessment; nearly all the agricultural counties exhibit a corresponding decrease.

—The Santa Fe shops at Albuquerque, N. M., are to be increased in size so as to give employment to several hundred additional men.

—Denver, Colorado, is considering the question of buying the Denver Water Co.'s property, or putting $5,000,000 into an independent municipal water supply.

—The close of the Colorado smelter strike makes business boom in the Centennial State, and everyone there is determined to see that the '99 record is even ahead of that of '98.

—The Mexican Government has awarded a contract for laying a cable from Altata, State of Sinaloa, Mexico, to Lapaz, Lower California, 114 miles, to be completed within six months.

—New locomotives are necessary for the increasing traffic over the Arizona & New Mexico Railway, connecting Clifton and Lordsburg, and the one between Clifton and Morenci; the latter is a 20-inch gauge.

—The Mexican Central management is building a new line south from the Guadalajara division to Zamona and points farther south; surveys for the proposed line from Ameca to the Pacific coast are being pushed.

—San Francisco has raised $55,000 to celebrate the return of the First California regiment from the Philippines. Three former employes of the MINING AND SCIENTIFIC PRESS, one of them now a captain, return with their regiment.

—On the Northern Pacific Railroad rails made by the basic open-hearth process have been put down experimentally, in which the phosphorus was limited to 0.05%, the carbon running up to 0.70%. So far the rails are reported to have done well.

—On the 19th inst. at Goldfield, Colo., the electrical power plant of the La Belle Mill, Water & Power Co. began. It will be used to operate the Florence & Cripple Creek and Golden Circle railroads and to supply power, water and light to the mines, mills and samplers of Cripple Creek district.

—The Arizona & Utah Railroad, a notice of the completion of which to Chloride, Arizona, appeared in this column last week, will continue on. In 100 days it will be to White Hills, fifty miles north of Kingman, will then cross the Colorado, proceeding along the Rio Virgin to St. Thomas, the ultimate intent being to connect with the Utah & Pacific R. R.

—The Southern California Power Co., Pasadena Electric Light & Power Co. and the Edison Electric Co. of Los Angeles, Cal., have consolidated. The Edison General Electric Company of Los Angeles is the name of the new company; capital stock, $1,250,000; 5% bonds to that amount will be issued. The new company has a three years' contract for lighting Pomona and will build a transmission line to Anaheim, Fullerton, Orange and Santa Ana.

—At Houghton, Mich., copper production is decreasing, though 5000 more men are employed than one year ago. Opening of new mines in Arizona draws workmen from the older properties. The product of unsmelted copper of the Quincy mine was less than 700 tons in July (an average of 800 tons had been maintained for a year previous), due to inability to find miners to get out the rock. With a total force of 1250 employes, the Quincy has at present less than 400 miners.

—Consul Macrum of Pretoria, South Africa, writes: "Referring to my report of June 13, 1899, in regard to the reconstruction of the Rustenburg and the Lydenburg Railways, I have to state that a notice has been published extending the time for the sending in of tenders on the construction of the Rustenburg line until Thursday, Oct. 12th next, at noon. This is done for the purpose of allowing foreign contractors time to bid and makes the time on both the Pretoria-Rustenburg and the Belfast-Lydenburg lines the same."

—California leather is in demand from Japan for harness and heavy work. There has been a steady importation there of horses to do heavy draft work. There is a scarcity of hides at present and California is importing from Australia. On the coast and in the Northwest the demand is mostly for fine-grained hides, but the transpacific trade calls for heavier, coarser goods. No hides come from South America, as these are all shipped down the rivers to the Atlantic and to New York and Boston or across the water. The Pacific coast line of South America does nothing much in cattle. California leather dealers do not handle horse hides, though parts of them make good shoe leather.

—The Comstock, Nev., Pumping Association have concluded that it would be unwise for the Comstock mining companies to attempt the erection of an electric power plant, and will close with the Truckee River Co. on the basis already outlined herein. The association has given the Risdon Iron Works of San Francisco a check for $5000, the fourth installment on their pumping contract: a total of $20,000 paid on the agreed sum of $30,000. This fourth payment of $5000 became due when the water in the C. & C. shaft had been lowered 250 feet below the Sutro Tunnel level, which distance was reached when the water stood at a point 29 feet below the 1950-foot level of the shaft. The water is now 35 feet below that level and still going down.

A BURNING OIL WELL, COALINGA DISTRICT, CAL.

A Burning California Oil Well.

The accompanying engraving is from a photograph kindly furnished by Mr. E. M. Hoagland of San Mateo, Cal. It graphically represents Home Oil Co.'s Well No. 4, Coalinga district, Fresno Co., Cal., as it appeared while on fire Aug. 1st, '99, and is believed to be the first picture of a burning California oil well ever published.

Personal.

RICHARD U. GOODE of the U. S. Geological Survey is in San Francisco.

JOS. CUMMING has been elected Mgr. Mechanics' Institute Fair at San Francisco.

JOHN LAWLER of Prescott, Ariz., owner of the Hillside mines, has gone to Florida for the summer.

H. W. STEVENS, a mine operator of Wickenburg, Arizona, is in San Francisco, Cal., on business.

JAS. ARGALL, formerly Supt. McCracken, Arizona, mine, is Mgr. Mexican mine, Groveland, Cal.

JOHN H. GARRETT, of Graham, Garrett & Co., is in Republic, Wash., examining mining property.

FRED WARD has been engaged as local manager of the Baltimore mine on Ni Wot Hill at Ward, Colo.

W. B. HANCOCK has gone to the Seven Devils, Idaho, district to begin work on the South Peacock mine.

JOS. LEITER of Chicago has dropped wheat, and, with a coterie of mining engineers, is looking at mines in southern Utah.

A. A. BLOW, who has been spending some time in the United States mining districts, is preparing to return to the Transvaal.

W. W. FISK, a Boston mining engineer, who has charge of a hydraulic mine in Sinaloa, Mexico, is in San Francisco to buy machinery therefor.

F. S. ROBBINS, E. M., in charge of McKenzie & Mann's interests in British Columbia, has returned to Greenwood, B. C., from an Eastern business trip.

H. DEAKYNE, First Lieutenant Corps United States Engineers, has been inspecting the debris dam built at the Red Hill hydraulic mine, El Dorado Co., Cal.

W. L. FISK, Major U. S. Engineer Corps, has been transferred to Portsmouth, N. H., from Portland, Or., relieving Col. C. R. Suter at the former place. He will be succeeded by Capt. Langfitt at the latter station.

H. J. REILING, president of the Pacific Dredging Co., was "held up" in a stage coach at Horseshoe Bend, Idaho, on the 21st inst., and robbed of $5000 in gold dust, the proceeds of a partial cleanup of the dredger work.

AT the annual meeting of the California Association of Civil Engineers in an Francisco this week, the following officers were elected: Pres., M. M. O'Shaughnessy; Vice-Pres., T. W. Morgan; directors—L. Bridges, F. T. Newbery, S. H. Smith, C. E. Moore, W. K. Miller; Sec., O. von Geldern; Treas., F. T. Newbery.

A. EKMAN of Oroville, Cal., has been appointed by the California World's Fair Commissioners to collect, install, maintain and manage the exhibit of California minerals at the Paris Exposition in 1900. Mr. Ekman had charge of the collection of minerals which Butte county, Cal., displayed at the Columbian World's Fair at Chicago and at the Midwinter Fair and Mining Jubilee, San Francisco. He is now securing mineral exhibits to be sent to Chicago, there to be classified and packed for export to Paris.

Commercial Paragraphs.

THE Colorado Iron Works of Denver, Colo., are building a 100-ton copper matte smelter for Cherry creek, Arizona.

LACY MANUFACTURING CO. of Los Angeles, Cal., are erecting a 35,000-barrel oil tank for the Coalinga Oil Co., Coalinga, Cal.

FRASER & CHALMERS have established sales offices at 1426-1429 Marquette Bldg., Adams and Dearborn Sts., Chicago, Ill. Their main offices will be located at their new works, Twelfth St. and Washtenaw Ave., Chicago.

IN addition to being sole Pacific Coast agents and builders of the Wilfley concentrator, the firm of White, Rogers & Co., 306 Pine St., San Francisco, Cal., supply and put in place modern mining machinery of all kinds.

MESSRS. HEWITT & REARDON, the Compressed Air Machinery Co., 11 and 13 First St., San Francisco, Cal., have a flexible metal hose, copper or steel, any required dimension, that should be of practical value to anyone using hose or tubing.

A CATALOGUE upon underground electric haulage has been issued jointly by the Baldwin Locomotive Works and the Westinghouse Electric & Manufacturing Co. Electric mine locomotives produced by such eminent manufacturers cannot fail to interest all mine proprietors who study economy in operating expenses. The catalogue illustrates and describes the locomotives and contains tables of dimensions and of the hauling capacity upon various grades.

THE Keystone Driller Co. of Beaver Falls, Pa., have shipped two of their placer testing machines to the Feather River district, Cal., one for a Philadelphia company and one for the New England Exploration Co. of Boston. They are shipping two more to the same general neighborhood for other parties; also, one to Ortiz, Sonora, Mexico. A machine was lately put to work for the Taylor Park M. Co. of Tin Cup, Colo. With their placer testing machines the Keystone Driller Co. are furnishing a new device for drawing the 6-inch pipe after the tests are completed. A dredger pump has recently been brought out by the Keystone Driller Co., which will take up the liquid mercury or amalgam from the bottom of a test well. It is automatic in operation, being lowered into the test well by means of a rope. It is used in connection with the placer testing machinery made by this company.

THE expanding commercial interests of Los Angeles, Cal., are typified in a factory such as that conducted by the Ready Rock Roofing Co., which produces a roofing not affected by sun heat, which can be laid at any pitch, and which will hold the gravel surface indefinitely. Mr. G. W. Ludlow is president of the company. The backing of this roofing is a piece of wool felt thoroughly saturated in asphalt. The asphalt used throughout the process is rock asphalt, produced by the Alcatraz Asphalt Co. Six or eight tons are treated at a time. The second layer of the roofing consists of burlap, which is immersed in the asphalt at 300° F., until every fiber is saturated. The felt and burlap are timed in their progress through the machine, so that the asphalt surface receives the gravel coating at the proper temperature. Later it reaches a set of rollers, the upper of steel and the under of rubber, adjusted to give the degree of pressure necessary to imbed the gravel evenly and firmly in the asphalt. The gravel used is a natural quartz gravel, which Mr. Ludlow states he has so far found nowhere except in Los Angeles. This fact, with the nearness to the asphalt mines, were the principal factors in locating the factory in Los Angeles. The use of this gravel obviates possibility of cutting the fiber of the burlap. The capacity of the present plant is sufficient to turn out a 40-foot roll, 2¼ feet wide, every two minutes. Several shipments have been made to Honolulu. The United Verde Copper Co. of Jerome, Ariz., have recently used a large quantity of it. Smith & Young handle it in San Francisco.

Notices of Recent Patents.

Among the patents recently obtained through Dewey, Strong & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

LIQUID RUDDER BALANCE.—J. Christensen, San Francisco, Cal. No. 620,973. Dated August 15, 1899. This invention relates to a governor for ships' rudders. It consists essentially in a novel arrangement of a cylinder or cylinders with piston movable with relation thereto, a piston rod connecting the main cylinder with a lever fixed to and movable with the rudder stock, and a means for transferring liquid from one side to the other of the piston within the main cylinder, and means for compensating for the difference between the two ends of the cylinder by reason of the space occupied by the piston rod upon one side of the piston. It also comprises means for replenishing the loss of liquid within the cylinders from time to time. With a device of this character connected with the stock of the rudder, the shocks caused by the action of the sea in heavy weather are prevented from being communicated through the steering gear on account of the resistance of the liquid moving through the small communicating passages, and while these passages do not prevent the slow movements from side to side when operated by the steering gear, they prevent its being suddenly dashed to one side or the other. The details or compensating for the different amounts of liquid required to fill the opposite ends of the cylinder and the means for supplying any waste make a very effective operating device.

CAN SOLDERING APPARATUS.—W. S. Case, San Jose, Cal. No. 630,591. Dated Aug. 8, 1899. This invention relates to an apparatus by which square cans are delivered into holders and caused to traverse a solder bath with means for rotating the cans at stated intervals so as to present each of the edges to be soldered while the can is passing through the bath. It consists of a trough for melted solder, a framework fixed diagonally with relation to the trough having a support in which the sides of the cans rest and a second support against which the bottom of the can rests so that the angular edges will be submerged in the solder. A device is employed for moving and turning the cans consisting of an endless traveling chain, shafts journaled transversely of the chain and in line with the axis of the can, arms fixed to the upper ends of the shafts and fixed stationary lugs with which the arms engage successively as the chains travel, thus turning the shaft at intervals to submerge the new edge of the can in the solder bath. A transversely slotted disk is fixed to the lower end of each shaft and a carrier head is loosely attached to the disk and movable radially with relation to it. Arms project from this head and are adapted to clasp the end of the can so that the movements of the head will allow the angular can to turn as it moves through the bath.

List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey, Strong & Co., Pioneer Patent Solicitors for Pacific Coast.

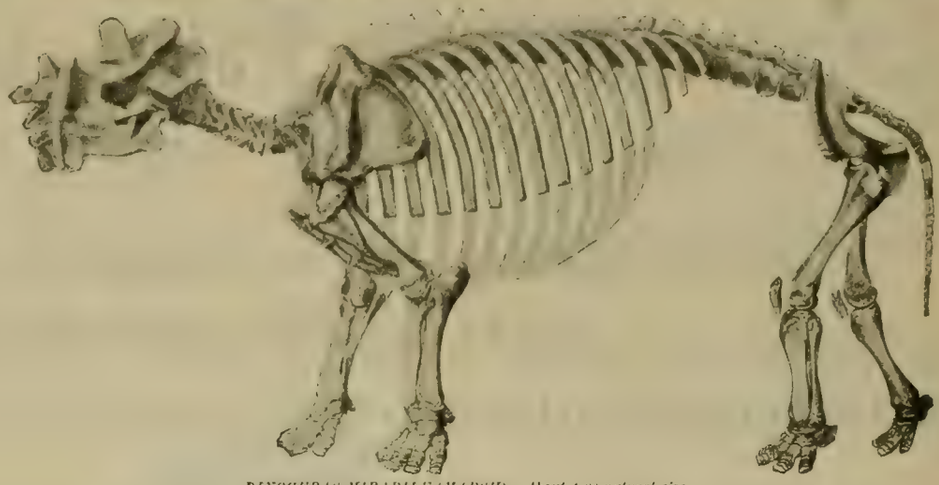
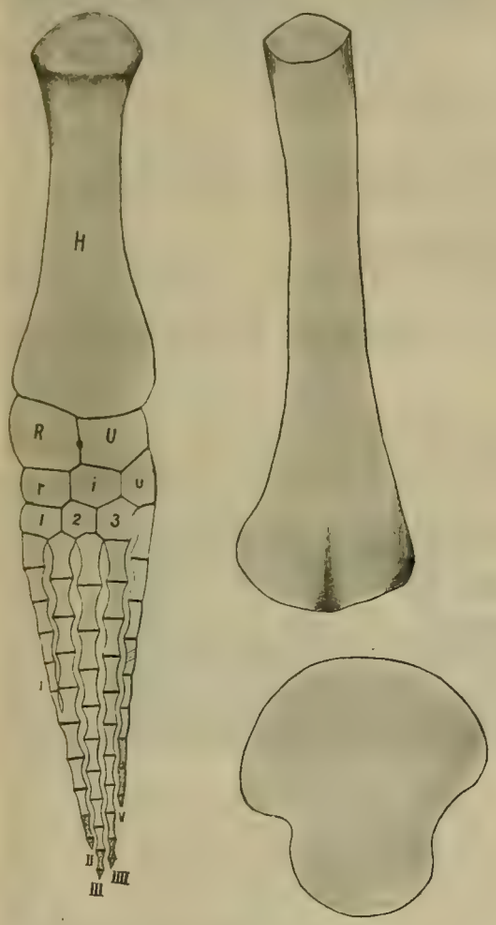
NOTE.—Plain and Certified Copies of U. S. and Foreign patents obtained by Dewey, Strong & Co., by mail or telegraphic order. American and Foreign patents secured, and general patent business transacted with perfect security, at reasonable rates, and in the shortest possible time.

Obituary.



ON the 19th inst. John R. Thom, Supt. Los Angeles mine, Bull Hill, Cripple Creek, Colo., fell from the fourth level to the bottom of the shaft, 200 feet, and was instantly killed. There were no chains, bars nor lights at the mouth of the drift, and their absence caused his death.

The Gigantic Fossils of Wyoming.



The extinct animals being found under the plains of Wyoming do not cease to be a wonder. Other lands have produced huge mammals and strange reptiles, but none ever previously discovered can equal or approach those of the Cretaceous and Tertiary beds of southeastern and central Wyoming. Under the auspices of the Union Pacific Railroad a large party of men from numerous colleges and universities, headed by Prof. Wilbur C. Knight of the Wyoming University, is now delving into the sandstone and clays for the fossil remains of these immense animals long since extinct. Herewith are illustrated two of these monsters with the individual bones of several others. At one time Wyoming had numerous fresh water lakes and a semi-tropical climate, at which time these animals appear to have dwelt in the swamps and lakes in great numbers. Dying, they sank in the mud flats, and accumulating deposits covered the remains, the bony parts of which were turned to stone. These are called fossils. Birds, fish, trees, leaves and other forms of organic life have been preserved in like manner. The tracks made by animals in the soft mud are also often found and ripple marks of waves and even the imprint of rain drops can sometimes be seen with wonderful distinctness.

P & B ROOFING

ROOFING is to a building what clothing is to the body. It must protect and it must wear well. To put money in an interior and to save it on the roof of a building is poor economy.

P & B ROOFING possesses all the requirements of a first-class roof covering. It is waterproof, durable, inexpensive, easily laid. Ask your dealer for a circular, or address the makers.

THE : CAMMETT : CONCENTRATOR.

Designed with some Regard for the Laws of Concentration.

The perfect vanner motion given to the pulp by our head motion, together with the freedom from "jumping" resulting from the special rigid guides used, explains why the Cammett riffles never "pack," and why the table has such a great capacity when handling slimes.

The continuous grooves and riffles extending from end to end of the table maintains the greatest possible margin of safety between the concentrates discharge and the tailings.

Thoroughly Protected by Strong Patents. Write for Circular.

ADAM SCHILLING & SONS, 211 & 213 MAIN STREET, SAN FRANCISCO, CAL.

Double-Jointed Ball-Bearing Hydraulic Giants.

The above presents an improved **Double-Jointed Ball-Bearing Hydraulic Giant** which we build. The improvement consists of the introduction of a **Ball Bearing** by which the pressure of the water is reduced to a minimum and the direction of the nozzle changed at will with ease.

Catalogues and prices of our specialties of HYDRAULIC MINING MACHINERY furnished upon application. **JOSHUA HENDY MACHINE WORKS, 38 to 44 Fremont St., San Francisco Cal.**

THE

"Pneumatic" Cyanide Process.

(Patented in United States, South African Republic, New Zealand, Victoria, New South Wales, South Australia; other patents pending.)

Supplies the solution with the oxygen required for perfect extraction. Prevents settling, packing and channelling. Heats the solution and prevents freezing in winter. Doubles the capacity by requiring less than one-half the usual time. Saves the highest percentage of values at the lowest cost per ton. *"Mill rights" sold direct to users; no royalties.*

Send for pamphlet to THE PNEUMATIC CYANIDE PROCESS CO.,

PATENT SOLICITORS,

330 MARKET STREET, - SAN FRANCISCO, CAL.

Inventors on the Pacific Coast will find it greatly to their advantage to consult this old experienced first-class agency. We have able and trustworthy associates and agents in Washington and the capital cities of the principal nations of the world. In connection with our scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of patents already granted, for the purpose of determining the patentability of inventions brought before us, enables us to give advice which will save inventors the expense of applying for patents upon inventions which are not new.. Circulars and advice sent free on receipt of postage. Address **DEWEY, STRONG & CO., Patent Agents, 330 Market St., San Francisco, Cal.**

General Arrangement of Pelatan-Clerici Plant.

The "Pelatan-Clerici" Process

OF TREATING REFRACTORY ORES

Saves the precious metals by the simplest, most economical and most efficient process known. No roasting or previous treatment, except ordinary crushing. Extraction complete in from 6 to 12 hours. Extracts equally well both fine refractory gold and coarse gold in the form of amalgam. Makes a greater saving of gold than any other process from raw material at less cost. The electric current and dissolving agent promptly dissolve the precious metals, both gold and silver. Samples of ore tested free of charge. Several mills saving over 90 per cent of values by bullion returns. Simplicity. Economy. Efficiency.

The most modern, completely equipped and up-to-date plant in the Northwest. Everything new from end to end.

GATES FINE CRUSHER.

The result of ten years' solid work. Success at last. What we wanted, and the public demanded, was a Gates Gyratory Rock and Ore Breaker (always adjustable and indestructible) so modified in design as to make one-half-inch product from three-inch sizes, rapidly and cheaply. The H Fine Crusher will do this work. It takes the place of expensive big rolls and often prepares ore, without further crushing, fine enough for coarse concentration or cyaniding. In any event, it is the greatest and best intermediate machine between the coarse breaker and the pulverizer.

Ask for No. 1 Catalogue. :: GATES IRON WORKS, Dept. UU, 650 Elston Ave., CHICAGO.

Assessment Notices.

CENTRAL EUREKA MINING COMPANY.—Location of principal place of business, San Francisco, California; location of works, Sutter Creek, Amador County, California.

Notice is hereby given that at a meeting of the Board of Directors, held on the 25th day of July, 1899, an assessment (No. 13) of three cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin to the secretary, at the office of the company, room 9, 320 Sansome street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 1st day of September, 1899, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on MONDAY, the 25th day of September, 1899, to pay the delinquent assessment, together with the costs of advertising and expenses of sale.

By order of the Board of Directors.
WM. A. M. VAN BOKKELEN, Secretary.
Office—Room 9, 320 Sansome street, San Francisco, California.

MARIPOSA COMMERCIAL AND MINING COMPANY.—Location of principal place of business, San Francisco, California; location of works, Mariposa County, California.

Notice is hereby given that, at a meeting of the Board of Directors, held on the 28th day of July, 1899, an assessment (No. 12) of ten ($10) dollars per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the secretary, at the office of the company, 320 Sansome street, room 24, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 5th day of September, 1899, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on FRIDAY, the 29th day of September, 1899, to pay the delinquent assessment, together with the costs of advertising and expenses of sale.

By order of the Board of Directors.
JOSEPH H. MOOSER, Secretary.
Office—320 Sansome street, room 24, San Francisco, California.

EUREKA CONSOLIDATED DRIFT MINING COMPANY.—Location of principal place of business, San Francisco, California; location of works, Forest Hill Divide, Placer County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 10th day of August, 1899, an assessment (No. 20) of one-half cent per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the secretary, at the office of the company, No. 1209 Claus Spreckels building, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 12th day of September, 1899, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on SATURDAY, the 30th day of September, 1899, to pay the delinquent assessment, together with the costs of advertising and expenses of sale.

By order of the Board of Directors.
J. J. CRAWFORD, Secretary.
Office—1209-11 Claus Spreckels building, San Francisco, California.

NATIONAL CONS. MINING COMPANY.—Location of principal place of business, San Francisco, California; location of works, Rich Gulch, Shasta County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 9th day of August, 1899, an assessment (No. 8) of ten (10) cents per share, was levied upon the capital stock of the corporation, payable immediately in United States gold coin to the secretary, at the office of the company, No. 773 Mission St., San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 18th day of September, 1899, shall be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on WEDNESDAY, the 11th day of October, 1899, to pay the delinquent assessment, together with the costs of advertising and expenses of sale.

By order of the Board of Directors.
GEO. W. FLEISSNER, Secretary.
Office—773 Mission St., San Francisco, California. Office hours from 1 to 3 P. M.

ORLEANS MINING COMPANY.—Location of principal place of business, San Francisco, California; location of works, Grass Valley, Nevada County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 31st day of July, 1899, an assessment (No. 9, new series) of five (5c) cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the secretary, at the office of the company, 324 Pine St., San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 8th day of September, 1899, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on TUESDAY, the 3rd day of October, 1899, to pay the delinquent assessment, together with the costs of advertising and expenses of sale.

NO MORE PACKING DIRT TO WATER.

—THE—

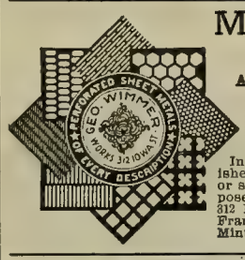
PNEUMATIC PROSPECTOR.

Size 6x11x14 in. Weight only 10 lbs.

PACKED FOR MOVING.

NO WATER NEEDED.

Gives a clean prospect from placer ground or free-milling ore by compressed air. The operation is purely mechanical. No chemicals, no quicksilver; no black sand remains with the gold. Will do work equal to careful panning.



THE PNEUMATIC SEPARATOR.

Weight 160 lbs.

Has a capacity of 20 to 30 cu. yds. of gravel per day. Will save fine and coarse gold and nuggets of any size, comparatively free from black sand. Will do better work under favorable circumstances than a sluice box. Indispensable for dry countries.

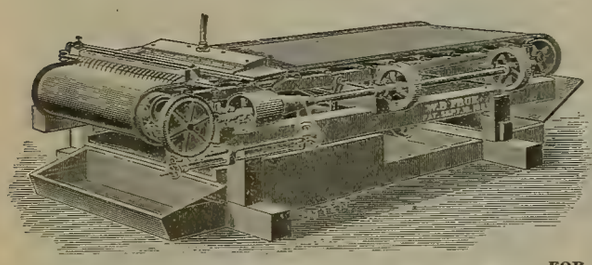
MINE BELL SIGNALS.



Adopted, Used and in Force in Accordance with Law.

We print in legal size, 12x36 inches, the Mine Bell Signals and Rules provided for in the Voorhies Act passed by the California Legislature. The law is entitled "An Act to Establish a Uniform System of Bell Signals to Be Used in All Mines Operated in the State of California, for the Protection of Miners." We furnish these Signals and Rules, printed on cloth so as to withstand dampness. 50 Cents a Copy.

MINING AND SCIENTIFIC PRESS, 330 Market St., San Francisco, Cal.

FOUR and SIX-FOOT FRUE VANNERS

With Brownell "Patent Lip" Flange Belts.

STANDARD MACHINE OF THE WORLD.

When a Concentrator like the Frue Vanner has been on the market nearly two decades, and the sales have constantly increased, it is safe to say it is the "Standard Machine of the World." More Frue Vanners have been sold during the last twelve months than for the same period at any time during the history of the machine. Practical mining men in all parts of the world where mining is carried on will testify as to its merits. It is the "standard" which all competitors are trying to imitate.

The results obtained by this machine are the "acme" of concentration, and several cheap and untried machines that have lately come on the market compare by it. The manufacturers will tell you that they are "just as good, and cheaper," etc. The facts are that no other concentrator made has an equal capacity, or will yield as clean a concentrate with as small loss in the tailings as the Frue Vanner. The amount saved from the lower first cost of an inferior machine counts little in the year's results, when compared with the increased output from a Frue. This machine not only gives better results at both ends of the belt (i. e., clean product and poor tailings), but is operated at less expense and requires less attention than any other machine on the market. At the Alaska-Treadwell mine, where they have ordered over 350 Frue Vanners, one man attends 48 machines for 12-hour shift.

FOR DESCRIPTIVE PAMPHLETS, ADDRESS

J. S. BROWNELL, Western Agent FRUE VANNING MACHINE CO.,

132 MARKET STREET, (Successor to Adams & Carter.) SAN FRANCISCO, CAL.

RISDON IRON WORKS,

SAN FRANCISCO, CALIFORNIA.

Cable: "Risdon's." Code: A. B. C. & Leiber's.

RISDON IRON WORKS SAN FRANCISCO, CALIFORNIA.

MANUFACTURERS OF

Gold Dredging Machinery

And COMPLETE EQUIPMENT for Placer Mines

OUR SPECIALTY.

We build **GOLD DREDGES COMPLETE IN RUNNING ORDER** to handle 2500 cubic yards per day at a cost of 3 cents per cubic yard.

We excavate 50 feet below water, 20 feet above water and handle boulders up to one ton weight.

Send for Dredging Catalogues Nos. 15 and 16.

WE ALSO BUILD

All kinds of Mining, Milling, Concentrating, Pumping, Air Compressing, Hydraulic, Water Wheel and Hoisting Machinery.

EVANS HYDRAULIC GRAVEL ELEVATORS.

We publish sixteen catalogues. Write for one in the line you are interested in.

THE HALLIDIE ROPEWAY,

For transporting Ore, Fuel, Merchandise, etc., in bulk or in packages. SIMPLE, ECONOMICAL, INEXPENSIVE, PRACTICAL.

LOADS MECHANICALLY. DUMPS AUTOMATICALLY. Send for Ropeway Pamphlet No. 20.

THE CALHOUN EXCAVATOR.

A Combined Power-Shovel and Cableway. ASK FOR CIRCULAR.

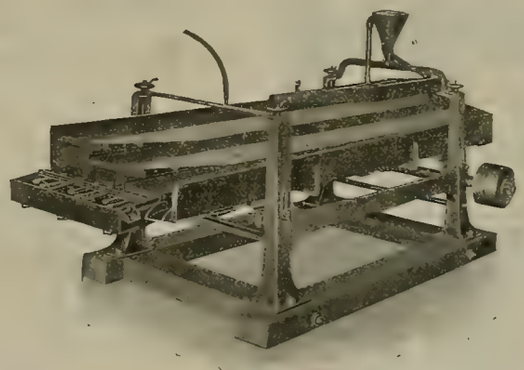
Cableways, Incline Planes, Double Rope Tramways, Wire Rope Transmissions, Logging Machinery, Suspension Bridges,

DESIGNED, FURNISHED, ERECTED. Write for Estimates.

CALIFORNIA WIRE WORKS, 9 Fremont St., San Francisco, Cal.

THE BARTLETT CONCENTRATING TABLE.

One of these Machines will take the place of TWO or THREE Belt Concentrators of any make and do as good work.



Separates ALL the minerals from each other at one operation.
Gives THREE CONCENTRATES on the one Machine at the same operation.
The Machine is especially adapted to the separation of Zinc and Lead.

- PRICE: -

12-ft. Table, $350.

SHIPPING WEIGHT - - - - - 2200 POUNDS.

CAPACITY - - - 10 to 30 tons per 24 hours.

Parties desiring tests made can send 500 lbs. or more, charges prepaid, and a run will be made and reports forwarded of the results, free of all charges, except for the assays, which will not exceed $10.00.

CAN BE SET UP ANYWHERE.

REQUIRES NO SPECIAL FOUNDATION.

Licensee for the Manufacture and Sale, **PARKE & LACY CO.,** 21 & 23 FREMONT STREET, San Francisco, Cal.

AGENT FOR

KNOWLES PUMPS and PULSOMETER PUMPS,

INGERSOLL-SERGEANT ROCK DRILLS and AIR COMPRESSORS.

CATALOGUES FREE ON APPLICATION.

No. 2043.—VOLUME LXXIX. Number 10. SAN FRANCISCO, SATURDAY, SEPTEMBER 2, 1899. THREE DOLLARS PER ANNUM. Single Copies, Ten Cents.

Coal of the Crow's Nest Pass.

The discovery and development of coal in Crow's Nest pass in Southeast Kootenay in 1897–98 is considered by the Minister of Mines of British Columbia as one of the most important developments in the province, for the reason son that it can supply the mining region of East and West Kootenay with a cheap, serviceable coal without breaking bulk, delivering the cars at the various mines. Thirty-four coal seams are known to exist in the several basins, and these afford two varieties of coal—bituminous and cannel coal. The Elk River series outcrops along the mountains on the east side of Elk river, from Morrisey creek to above Coal creek, at 1600 to 2500 feet above the valley of Elk river, the beds dipping easterly into the mountain at a low angle. These are the only ones thus far developed. In thickness the veins range from 4 to 30 feet, three of them being in the latter class and one is 15 feet. The coal veins are intercalated with sandstones, conglomerates and shales. The deposits are extensive, reaching for miles.

BRIDGE CONNECTING TUNNELS, CROW'S NEST COLLIERIES, KOOTENAY, B. C.

During 1898 tunnels No. 1 and No. 2 of the Crow's Nest Coal Company were connected by a trestle 1000 feet long, a view of which appears on this page, which was kindly loaned by Mr. Mortimer Lamb of the *British Columbia Mining Record*. Complete shaking screens have been built about the center of the trestle. At Fernie a number of coke ovens have been built and the company announces its intention of putting up 200 of the beehive pattern.

Moyie lakes are a widening of Moyie river. The town of Moyie is on the eastern shore of the most southerly of these lakes. The country rock of the vicinity is composed of gray slates and shales, with beds of quartzite dipping about 15° easterly. On the mountain above the town a number of locations have been made, among them the St. Eugene mine. On the opposite side of the lake is the Amora group. The veins at Moyie cut the stratified rocks and carry galena, being heavily mineralized in places. Bull river heads in the Rockies and empties into Kootenay river near Wardner, B. C. In early years considerable placer gold was taken from various parts of the stream, but no one has yet been able to locate the veins or formation from which the placer gold, which was rich, came. The country rock consists of alternating strata of hard, dark slates and quartzites. Near the head of the canyon the rocks are much disturbed and folded, as shown in the accompanying engraving. There are very few veins cutting the slates, and none which carry free gold. Two large dykes, parallel and several hundred feet apart, cross the river above the canyon and on one of these numerous locations have been made. Excavations on this dyke showed galena in the porphyry.

TABLE OF CONTENTS.

ILLUSTRATIONS.—Bridge Connecting Tunnels, Crow's Nest Collieries, Kootenay, B. C.; Bull River, Kootenay, B. C., Showing Strata; Moyie City, Kootenay, B. C., 253. Automatic Sampler for Slimes, 256. Buffalo Hump, Idaho, Looking West from Concord Townsite, 258. Latest Mining and Metallurgical Patents, 259. The Junkers Gas Calorimeter; Junkers' Calorimeter for Liquid Fuels, 260.

EDITORIAL.—Coal of the Crow's Nest Pass, 253. Some of the Reasons; Mineral Production of the United States; Miscellaneous, 254.

MINING SUMMARY.—261-262-263.

THE MARKETS.—The Local Markets; Mining Share Market; Sales in San Francisco Stock Board, 278.

MISCELLANEOUS.—Concentrates, 255. Notes on Sampling, Analyzing and Treating Slimes, 256. Mining Definitions; Across the Pitch Versus Up the Pitch; State and Federal Mining Law, 257. The Buffalo Hump District, Idaho; The Lucknow, N. S. W., Gold Field, 258. Latest Mining and Metallurgical Patents, 259. Measuring Gas and Liquid Fuel; Some Experiences of a Working Miner, 260. Industrial Notes; Personal; Commercial Paragraphs; Catalogues Received; List of U. S. Patents for Pacific Coast Inventors; Notices of Recent Patents; Recently Declared Mining Dividends, 263-264. Average Life of Iron or Steel Bridge; America Leads as a Producer of Iron and Steel; The Sequoias of the Sierra; The Largest Vessel Afloat, 265.

Some of the Reasons.

"If your mine is so good; if the prospect is so favorable, why don't you work it yourself, and if you don't do that why don't you get some one from your own city, State or country to buy it or take hold of the project? It must be that the property can not be what you represent it or it would not be necessary to bring it over here."

The above is what is often heard by anyone who proffers a meritorious mining proposition in the East, or England, or elsewhere. It is not an unnatural view, and deserves consideration.

The ordinary reason why an ordinary mine owner or prospector does not develop his own property is that he hasn't the money: if he had he wouldn't be offering the property, but would work it himself, yet this is no fair argument against the value of the property, for mines are made, and usually require considerable money to be properly started. It is the same with nearly every enterprise or business. Whether it be a railroad, a manufactory, a newspaper, a mercantile establishment, a bank, or anything else requiring much money, it will usually be found that the enterprise is not started nor run by individual capital, but that the collective contributions of hundreds of people have gone into the necessary fund that made the plan possible. It would be as reasonable to ask a man suggesting the taking of a slice of stock in any other promising proposition: "Why don't you start this thing yourself?" as to suggest the same objection to the man seeking to sell what is ofttimes more likely to develop into a dividend payer than any other corporation or partnership plan.

Again, because a mine is proffered to a foreign capitalist, it is no evidence that it is worthless or not wanted nearer home, or not considered worth having. This latter objection is the most constant, yet most inconsistent, of any. It is based on a wrong conception of facts. If there were only 200 or 300 mines or undeveloped prospects in the country, and these had been sized and sifted by home purchasers or local investors, the best absorbed and the worst neglected, it would be fair to infer that it was one of the latter class that was being offered. But it is a case of "oversupply." Local residents are not numerous enough to take all the opportunities, however promising. While thousands of millions of dollars have been and are being locally invested in mine property, as much more could be so invested to advantage. Take the case of California. It is sometimes said at home and abroad, with a sneer: "Why doesn't San Francisco invest? If you have so much valuable mining area, the people there would be likely to keep it as too good a thing to be let go."

There are thirty-seven gold-producing counties in the 156,000 square miles of California's area. San Francisco has been investing money in mines for fifty years and is to-day more heavily interested in mines in California and elsewhere than ever before. In one county in California, San Francisco has put over $5,000,000 in the last three years. There are few mining districts in any part of the west half of America in which San Francisco capital is not invested, but ten San Franciscos could not furnish the requisite amount of money necessary to develop the multitude of deserving mining projects daily brought to its attention. What is said of San Francisco applies with even greater aptness to Denver, Salt Lake City, Spokane and other cities. There are mines of merit in Colorado that cannot find capital in Denver to push them onto a stage of development that would make them big-paying propositions, not from any distrust in Denver of their value, not from any local knowledge that would cause refusal, but purely because of the multiplicity of such proffers. Denver is a rich and progressive city, and its people are not slow to seize opportunities for making money quickly in mines or any other legitimate form of investment; but were Denver a dozen times as rich and enterprising and ready to invest every available dollar in good mines in Colorado alone, the supply would exceed the possibility of such investment. And as in San Francisco and Denver, so in Salt Lake City. The writer recently sojourned in the Utah metropolis. Remembering it when it was a little adobe-built settlement, he noted with pleasure the buildings, the large hotels, stores and fine private residences, the air of growing wealth evident in every quarter. It was manifestly due to the mining element. Every mining company operating in Utah, except four, has its headquarters in Salt Lake City; to Salt Lake goes much of the proceeds of the mines; from Salt Lake went much of the money that opened up those mines and made prosperity in mountain and desert. Yet there are promising prospects enough in Utah—embryo mines that will some day be big dividend payers—to absorb every dollar that Salt Lake could raise in the next ten years.

So, likewise, it might be truthfully said of a score of other places west of the hundredth meridian. They have invested and are making money from such investments in mines, but can not absorb what is proffered, no matter how confessedly good they may be, from sheer lack of capacity; it is not the inclination, but the ability that is wanting. What wonder then that the man who knows he has a good thing, but lacks the money to develop it, failing to enlist local aid turns to the East or to Europe where money brings but 4%, in the just belief that there he can find a purchaser for or a co-operator in a mining property of value. It is not from any intent to "unload" or "work off" a questionable scheme, but in as honest a purpose as the man who in any other line of business, having only $10,000 and seeing where an investment of $20,000 would bring promise of making $200,000, asks one who has the money if he is willing to put up $10,000 with him in the venture.

The magnitude of the mining area of this country is not generally understood, still less is its value. Since the discovery of gold in California, that one State has produced gold to the value of over $1,300,000,000. There are now over 17,000 undeveloped mines in California awaiting capital to become profitable producers; fifteen years ago Cripple Creek district, Colo., was "good only for sheep grazing:" in the past two years the gold output of that sheep pasture has put Colorado in the front rank of the gold producing States of the Union. Yet there are over 15,000 undeveloped mines in Colorado. As in California and Colorado so in other States and Territories west of the hundredth meridian of west longitude.

Without decrying any metal producing region and with full recognition of the importance of other gold fields, it is believed to be a conservative statement fully justified by fact, to say that nowhere on the globe is there a better prospect for profitable investment in that form of business than in this region, and why such opportunity is proffered distant residents is manifest in the foregoing.

Mineral Production of the United States.

A summary of the mineral production of the United States in 1898 has just been issued by the United States Geological Survey. The production since 1880 has increased from $369,319,000 to $697,880,002 in 1898—nearly 90%—a normal increase of $18,000,000 per annum; but since 1893 it has been at the rate of $25,000,000 annually. A study of the tabulated statement shows some peculiar features. From 1894 to 1895 the increase was nearly $100,000,000, and in the following year it was but $1,000,000, while in the two years from 1892 to 1894 there was a decrease of over $121,000,000, owing to business depression. The total of $697,880,002 in 1898 was the largest ever recorded in the history of the United States.

The great increase came from all branches of the mineral industry, owing to greatly increased industrial activity with a consequent demand upon the mineral industries, nearly every one of them showing a gain. The metallic minerals produced were valued at $344,096,130; all of the metals, except nickel, making gains; copper, lead, zinc, aluminum and antimony during this period reaching their maximum in both quantity and value. The amount of pig iron produced was larger than in any previous year, though the value of the product was less than in 1890 or 1892. The nonmetallic products increased from $327,710,966 to $352,783,872, a gain of over $25,000,000, the largest factor being bituminous coal, which gained more than $13,000,000 over the production of the previous year.

The following table shows the value of the principal mineral products for the last two years:

	1897.	*1898.*
Pig iron	$95,122,299	$116,557,000
Silver	69,637,172	70,384,485
Gold	57,363,000	64,643,000
Copper	54,089,180	61,849,132
Lead	14,885,728	17,345,775
Zinc	8,498,300	10,385,910
Quicksilver	993,445	1,188,627
Aluminum	1,500,000	1,716,000
Antimony	109,655	184,050
Nickel	7,823	4,694
Platinum	900	1,913
Bituminous coal	119,567,224	132,586,313
Pennsylvania anthracite	79,301,954	75,414,537
Stone	34,667,772	36,607,264
Petroleum	40,929,611	44,183,350
Natural gas	13,826,422	14,750 000
Brick clay	8,000,000	9,000,000
Clay (other than brick)	1,000,000	1,000,000
Cement	8,178,283	9,781,501
Mineral waters	4,505,630	8,051,933
Phosphate, rock	2 673,2?2	3,455,460
Salt	4,920,020	6,212,554
Limestone for iron flux	2,124,000	2,638,000
Zinc, white	1,750,000	2,310,000
Gypsum	755,864	755,280
Borax	1,080,000	1,120.000
Mineral pa'nts	785,793	694,856
Grindstones	368,058	489,769
Fibrous talc	396,936	410,430
Asphaltum	664,662	675,649
Soapstone	365 629	287,112
Precious stones	139,675	160.920
Pyrite	391,541	577,731
Corundum and emery	106,574	275,064
Oilstones, etc	149,970	180,738
Garnet (abrasive)	80,853	86,850
Bromine	129,094	126,914
Fluorspar	37,159	63,050
Feldspar	43,100	32,395
Manganese ore	95,505	129,185
Flint	26,227	42 670
Monazite	1,980	12,462
Graphite	54,277	75,200
Bauxite	57,652	75,487
Sulphur	45,590	32,950
Fuller's earth	112,272	106,500
Maris	30,000	30.000
Infusorial earth, tripoli	22,835	16,691
Pumice stone	.....	13,200
Millstones	25,932	25,934
Cobalt oxide	31,232	11,772
Magnesite	13,671	19,075
Asbestos	6,450	10,300
Rutile	350	700

THE Spenazuma Mining Company, which came into unpleasant notoriety a few weeks ago through the expose of Governor Murphy of Arizona, has filed amended articles of incorporation and increased its capitalization to $10,000,000. Three gentlemen of Deming, New Mexico, whose names are mentioned as directors, repudiate the concern and deny that they are directors. This is the concern which was visited by Eastern directors, who came out in a special car in June last, and to whom was shown a dump of fine ore which, it was alleged, had been hauled from rich mines elsewhere.

DURING the recent whirlwind of flame that swept through Victor, Colo., while the buildings of the Gold Coin M. Co. were still blazing, the management ordered a complete new equipment, including steel buildings and a fireproof outfit throughout, demonstrating their faith in the property, and, in general, illustrating the good grit of the Colorado miner, who does not allow so slight a thing as total destruction of his surface improvements to more than temporarily interfere with his plans.

Concentrates.

GARNET is sometimes used for abrasive purposes, but is inferior to corundum and emery in hardness.

THE Government of the United States has no standing reward for tin or mineral deposits of any character.

THE nickel supply of America is chiefly supplied by Canadian mines. Most pyrrhotite ores contain nickel, though all do not.

NEARLY all the metallic tin produced comes from the oxide cassiterite which is derived partly from veins and partly from "stream tin."

A QUARTZ mill should be so arranged as to afford the greatest capacity at the least expense, employing no more men than are necessary.

CONGLOMERATE DEPOSITS bearing gold are really cemented placer mines, whether formed in the bed of a stream or on the slope of a hill.

DENVER, COLO., papers state that a New York firm has contracted with the owners of the Louisville mine for 10,000 tons of zinc ore to be shipped to Wales.

THE United States mining laws do not require that a location of a quartz or placer claim be recorded, but State, territorial or local laws may require such recordation.

THE production of crude petroleum in California for the calendar year '98 was 2,257,207 barrels, valued at $1,917,596. The '97 production was 1,903,411 barrels, valued at $1,713,102.

THE gates or valves controlling water in pipes should not be closed too suddenly, as the movement of the column of water when suddenly checked subjects the pipe to great strain.

A "SPILL OVER" is the language of the ancient river channel miner, signifies a place where erosion has cut into the bed of the former river the gold being reconcentrated in the modern gulch.

WHEN a load is to be lifted from a shaft in a bucket or skip or on a cage there should be no slack in the rope, or, if there is, the engine should be started so slowly as to take up the slack without a jerk.

IN the States of Pennsylvania, New York and West Virginia there were completed 7205 new oil wells in 1897; in 1898 there were 5574, and to the end of July, 1899, in the same area, 4426 wells.

THE cost of working auriferous sulphides by chlorination varies with the surrounding conditions. In California, where this method is practiced extensively, the cost varies from $5.50 to $13 per ton.

IN June, 1897, Judge Ross, in the U. S. Circuit Court, decided that the Caminetti Act was constitutional. On appeal, in May, 1898, Judge Hawley, in the U. S. Circuit Court of Appeals, affirmed the decision.

THE death of several men in different mines within the month just past from striking missed holes when drilling demonstrates the necessity for the exercise of greater care on the part of foremen or of the men themselves.

THE South African Chemical & Metallurgical Society states that ground glass is a most excellent flux for cyanide slimes. The charge for melting is 50 lbs. white glass and 50 lbs. borax to each 100 lbs. of roasted slimes treated.

FOR some purposes rolls are considered superior to stamps, particularly where the ore contains a large amount of sulphide material, which is to be concentrated by jigging. The rolls produce a more uniform product, making less slimes.

NUMEROUS samples of mica and inquiries concerning value of same are frequently received. Inquiries regarding commercial value directed to A. O. Schoonmaker, 158 William street, New York City, will meet with definite response.

AN English court, being recently required to define the word "mineral," held that the word "includes every substance which can be got from underneath the surface of the earth for the purpose of profit," which is no definition at all.

IT is cheaper to break soft ground and timber it than to break hard ground which requires no timbering. This applies only to first cost, for eventually the soft ground will require retimbering from time to time making it finally the more expensive.

THERE is a difference between relocation of a mining claim to correct errors made in the original location and relocation made for the purpose of defeating the law requiring an annual expenditure of $100, and this difference is recognized by the courts.

U. S. GOVERNMENT statistics for '98 place the mineral production of this country at a value for that year of $697,880,002, an increase of nearly 90% over the aggregate production of '90. Of the '98 total, the metallic product was valued at $344,096,120.

THE cheapest way to prospect large ore zones is by use of the diamond drill. By it the size, position and value of ore deposits may be determined at much less expense than by any other method and this knowledge is of great advantage in laying out development work.

THE tailings from the old mill at El Dorado Canyon, Nevada, have become a compact mass of rock, resembling some of the volcanic tufas covering the ancient rivers of California. Where this deposit is washed by the Colorado, the stream does not affect it in the least.

OUT of 431 accidents in English coal mines in 1897 47.4% were caused by the caving of ground, and in the previous year the percentage was higher. Many such accidents are due to the lack of care on the part of the miners, who take too many chances in recovering timbers.

THE cost of boring oil and water wells varies greatly, being influenced by the character of the rocks through which the bore passes and by its physical condition and also by the kind of "rig" employed, and not to a small extent upon the experience of the operator.

THE gold output of the Transvaal, South Africa, for the first six months of '97 was 1,630,000 ounces; for the first six months of '98, 2,321,000 ounces; for the first six months of '99, 3,042,000 ounces. Were Oom Paul to carry out his threat to flood or blow up the Witwatersrand mines, the result would affect the financial world.

ONE method of separating alumina from bauxite is by heating with soda ash, forming aluminate of soda, which is separated by solution in hot water from the insoluble silica, oxide of iron and titanic acid. Bauxite is employed as a refractory material, particularly in lining furnaces.

GAS ENGINES that work all right at sea level or low altitudes sometimes develop difficulty at considerable height. The trouble is in the "compression pressure." A properly arranged compression plate will give a higher pressure and obviate any difficulty occasioned by altitude.

THERE are few ores where the gold is extremely fine which cannot be treated by either the cyanide or the chlorination process in one form or another. Each new trial on a new ore is in the nature of an experiment, and moderate success at first may be developed into complete success later.

WHERE the acidity of ore has to be neutralized before subjecting the ores to cyanide solutions, lime has been satisfactorily employed; the lime water being slowly added until the acidity is neutralized, as determined by litmus paper. No two tests may be the same. It is a matter for experiment.

AN instance has been noted where, after the continuous operation of a quartz mill for several years, the stamps were hung up and the mill remained idle for some time. When work was resumed more than half of the stems broke off just above the bosshead within a month, without apparent cause.

INCLINED shafts are more expensive than vertical shafts of the same size in similar rock, for the reason that more time is required in placing timbers, and in handling pumps and other machinery in the shaft. A larger quantity of material can be hoisted through a vertical than through an inclined shaft.

THE new proposed shaft of the Rand-Victoria mines, it is estimated, will reach the banket at 4170 feet if the angle of dip of the conglomerate be 30° and 4550 feet if it should be 35°. These figures are deduced from the Simmer & Jack workings and a bore hole on the Rand-Victoria property 2400 feet in depth.

NEVER run a crosscut tunnel when one on the vein can be driven. Follow your vein, and when you have pay ore stay with it until it is developed. Crosscutting in the neighborhood of the vein is always advisable. Good veins and shoots of ore have frequently been overlooked from neglect to perform this essential work.

A BISBEE, ARIZONA, copper mining company writes that it is "negotiating for a hoisting engine," and on the strength of that wants to sell treasury stock. Further information is vouchsafed that "a considerable quantity of ore is piled on the dump" and that is "subject to the inspection of visitors." What more could anyone want!

IN large stopes, where filling or other supports to roof or walls has been too long neglected, the settling of the ground often makes the discontinuance of power drills imperative because of the danger of falling rocks loosened by concussion. Proper precautions taken in sustaining the ground will usually obviate this difficulty.

THE gold bearing deposits of Mercur, Utah, occur in argillaceous deposits, in altered limestones and in eruptive rocks, locally called porphyry. The greater portion of the gold of the district is obtained by the cyanide process. It was originally a silver camp in 1871. These being exhausted the camp fell into decay but revived upon the discovery of gold.

IT is claimed that some of the banded onyx (aragonite) found at the Big Bug, Arizona, quarries is gold-bearing. This deposit is the result of the precipitation of large quantities of calcium carbonate from calcareous springs, which have now disappeared. They were in many respects similar to the Formation Springs of the Yellowstone National Park.

THE term "gasoline" is an indefinite one. Technically and with reference to its use in a gas or gasoline engine, it is a petroleum distillate, colorless, volatile and inflammable, with a specific gravity of .629 to .667 (95° to 88° Baume). A great deal of stuff is sold as "gasoline." It is not by the name but by the gravity that its quality or fitness is to be determined.

THE stamp mills of the Witwatersrand crush from 2.93 to 7.9 tons per stamp daily. The number of stamps in the mills ranges from 20 at Gray's Mynpacht to 280 at the Simmer & Jack. The 20-stamp mill has the largest capacity per stamp of any mill on the Rand. Many of the mills sort the waste from the ore. The percentage of waste ranges from nothing to over 42%.

WHERE a party relocates an abandoned claim the fixtures and improvements, not removed by the original locator, become the property of the new tenant, to whom the law gives exclusive possession of the ground, and the former locator having forfeited his right has no business upon the premises and therefore can remove nothing from it. All decisions in similar cases have been rendered in this direction.

"THE best mining exposition I ever saw is the advertising pages of the MINING AND SCIENTIFIC PRESS," is the opinion of a Prescott, Arizona, subscriber. He tersely expresses a great fact, and might add it is an exposition that costs purchaser and consumer less than the more cumbrous methods of exhibition where the things themselves have to be carried to be seen, and the people must go to see them.

WHERE a partner in interest in an unpatented mining claim dies and his heirs refuse to contribute the share of deceased toward the annual expenditure for assessment work, the surviving partner should complete the full $100 worth of work and notify the heirs or executors of the estate of deceased as provided by law, and in event of their refusal to contribute the one-half of such expense their names should be included in the advertisement; the property ultimately becoming the possession of the surviving partner.

THE quantity of water required to hydraulic 1000 cubic yards of gravel daily depends upon the available head, character of gravel and dump grade. No arbitrary quantity can be given without knowledge of the conditions. Free gravel washes much more rapidly than clayey or lightly cemented gravel, and a given amount of water under a high head will remove a larger quantity of gravel than the same amount of water under low head. The grade below the working face may be too light to carry off the debris to the full capacity of the water and head to wash it down.

IN the U. S. Circuit Court this week, Judge Morrow rendered a decision of interest to foreign mining corporations, to the effect that they must obey State laws. The case was one in which a New York corporation sought to foreclose a mortgage of $50,000 on a Nevada City, Cal., mine. The defense of the Californians was that the mortgage was not in accordance with the California law, which requires in such cases a two-thirds vote of the stockholders. Judge Morrow held that the mortgage was not valid by reason of noncompliance of the directors with such State requirement.

A PRECONCEIVED IDEA of the conditions under which a deposit of mineral should occur is not a safe basis for a prospector to adopt when searching for veins or ore deposits. It is known that veins and ore deposits occur in the formations of every age and in rocks of almost every description, therefore it is unsafe to search only for those conditions with which one has become familiar in some other field, but to investigate every kind of rock, disregarding the condition under which it occurs, for in this way only can the risk of overlooking deposits of value be diminished.

WHERE a stamp is not revolved by the successive lifts of the cam—slipping back to the same position with each drop—the difficulty usually lies in the cupping of shoe or die or both. Where a poor quality of shoes and dies gives this trouble it may sometimes be lessened somewhat by shifting the position of the dies in the battery. The best shoes and dies now made are so homogeneous that there is little excuse for using an inferior quality on the score of cheapness, for the best—that is, those which wear evenly the longest—are the cheapest because of the higher efficiency which their even surface affords.

PROCESSES for the treatment of ores which are enveloped in mysterious manipulations, secret fluxes and the like may, on general principles, be looked upon with suspicion, as well as those processes which extract more bullion than the fire assay shows the ore to contain. It is true that during a period of a month or a year the bullion returns from a mill may exceed slightly the theoretical value of the ore as determined by assays, but this does not frequently occur. When such is the case, it may be laid to the fact that the error is a mechanical one in taking samples which is not positively representative. The discrepancy is rarely due to faulty metallurgical operations.

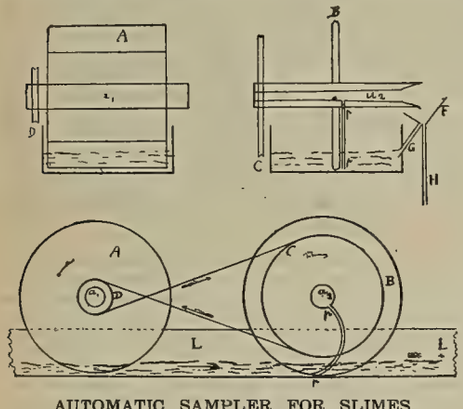
THE first use of the zinc ores of Missouri is said to have been made in 1869, though ore had been mined prior to that date, it being left on the dumps. The original discovery of lead ore was made about the year 1700. The zinc and lead deposits of the central and southeastern fields occur in Silurian rocks, and those in the southwestern district, about Joplin, in lower Carboniferous limestone. The ore bodies are massive, lenticular, tabular and rudely cylindrical in form. The minerals of these ore deposits are lead and zinc compounds, normally sulphides, and the results of their decomposition, chiefly the hydro-silicate of zinc (calamine) and the carbonate (smithsonite), and carbonate of lead (cerrusite) and more rarely the sulphate (anglesite) and phosphate (pyromorphite).

WHERE a mining claim is located in California after Nov. 2nd, it is possible to do the $50 worth of work required by the State statute of 1897 and make it a part of the $100 assessment work specified in the Federal statute. The 1897 mining law of California says that $50 worth of work shall be done on a claim within sixty days after location. The time when the $100 work required by the Federal statute must be done is during the year beginning on the 1st of the January after the date of location. So where a mining claim is located, say, Nov. 2nd, 1899, the locator has until Dec. 31st, 1900, to comply with the requirements of the Federal statute, and as he has until Jan. 1st, 1900, to do the $50 worth of work required by the State statute, he can make such $50 in work or improvements apply on the $100 required by the Federal law.

TO DETERMINE closely the cost of milling any particular ore is almost impossible without actual test, which must determine the most important economic features. The capacity per stamp is determined by the result of amalgamation. If coarse crushing does not give satisfactory results finer crushing is resorted to. It is a matter of judgment to determine where to draw the line as to fineness of crushing, the object being to get the greatest capacity with least loss. When the capacity per stamp has been ascertained the number of stamps which will determine the aggregate capacity becomes an important element, a large mill treating ore at a lower cost per ton than a small one. The matter of power is a third consideration. The cheapest available power will be chosen. Many mills are equipped with both water and steam plants, the latter being employed when water fails during dry season. There are many minor details in the mill construction which affect cost, as the size and distribution of rock breakers, method of handling tailings, etc.

THE forfeiture of a mining claim does not really follow because of non-performance of assessment work. It requires the intervention of a third party and a relocation of the ground before forfeiture can ensue. When such forfeiture becomes effectual the estate of the original locator is hopelessly lost. By resumption of work forfeiture may be prevented, but the resumption must be bona fide. The Supreme Court of California has decided that a party holding a claim for several years without doing in any year the work required, by simply going on the ground at the beginning of each year and doing a few hours' work, with no bona fide intent to comply with the statutory requirement as to the amount of work to be done, cannot hold the claim. Such work so done is a pretense and sham and will not prevent the relocation for want of necessary work. The Supreme Court of Montana has held that when a locator resumes work for the purpose of holding his claim he must continue the work with reasonable diligence until the law has been complied with. The right to resume work must be exercised, however, before another has taken possession with the intent to relocate it. The first initiatory step lawfully taken by a relocator after a claim becomes subject to forfeiture will protect him for the period fixed by law, and an intermediate resumption of work by the delinquent original locator cannot cut off this privilege.

Notes on Sampling, Analyzing and Treating Slimes.*



By L. EHRMANN.

To-day we have before us a slimes question, as in previous years we have had a cyanide question. We cannot even say yet that the cyanide question is closed, as we are still considering the proposals of heating solutions. The question of oxygen in solutions is also an important one, as you yourselves proved when presenting A. F. Crosse with the society's gold medal for his method of determining oxygen in cyanide solutions. By and by cyanide managers will have to test numbers of things—lime, oxygen, etc.,—not thought of some time ago, and will doubtless consider some members of this society very troublesome people. But science advances day by day, and I daresay the methods of treatment of slimes are still in their infancy. It has been started on the extreme dilution system, with electric precipitation by dynamos on lead cathodes. Now it seems we are coming to the period of concentration treatment and electrical precipitation by a primary cell being formed in the zinc boxes, so as to get rid of dynamos, lead cathodes and cupellation.

Anyway, electricity is to be, for a long time to come, the principal agent of precipitation of gold in the zinc boxes, as I explained to the society when I communicated my experiments on the zinc-copper couple in cold and hot solutions. As long as we are to employ cyanide as the solvent, there is little probability of arriving at a purely chemical precipitation of the gold without destruction of the cyanide; so we shall have, probably, to rely on zinc, as long as cyanide is used.

Now, zinc-lead couple, zinc-antimony couple, and some other improvements, are in the experimental or practical stage. Such processes are nothing else than electricity being generated in zinc boxes by a couple of zinc and some other metal; the question before us is to arrive at the maximum precipitation with a minimum of dissolution in zinc. We shall have to increase the activity of the zinc couple in weak solutions; and I think the question of slimes treatment will be settled, when gold from slimes solutions will be precipitated in zinc boxes with no more difficulty than from sands solutions, and recovered in the same way. It would be premature, at this period, to go more fully into this question, but I think I can say that we can see our way more clearly, thanks to the researches of some members of our society, and the alliance of theory to practice.

I begin with the question of sampling the slimes, and submit herewith description of an automatic sampler I have devised. A regular sampling of the

AUTOMATIC SAMPLER FOR SLIMES.

slimes passing down the launder is an absolute necessity to arrive at an accurate knowledge of the gold to be recovered. The method of sampling by a box placed in the launder is not a reliable one. The sampling in the collecting or dissolving vats has the objection of taking principally the lighter and finer portion of the slimes. For this reason I have devised the automatic sampler.

To an ordinary driving wheel *A* placed in the launder *L*, as in the automatic lime feeders, is connected—either directly or by an intermediate gear, so as to transmit the motion from the pulley *D* to the intermediate gear or to the pulley *C*—a flat disc *B*, perpendicular to a hollow axle a_2 and parallel to the axle a_1 of the driving wheel. To this is fixed an in-curved pipe *pp'*. At each revolution of the sampling disc *B* the lower part of the curved pipe plunges into the slimes from the top of the liquid to the bottom of the launder, then goes to the top again and is filled with a portion of the liquid slimes. By the revolution of the disc the sample is delivered in the hollow axle a_2 where the incline of the perforated central part is such as to cause the sample to flow at once to the prismatic funnel *F*. To this funnel is attached a double pipe, the one pipe *G* going back to the launder, the other *H* going to a tiny box or bucket where the sample for analysis is collected. In the prismatic funnel a moveable partition is placed, so as to divide the sample between the two parts of the double pipe in such quantities as are desired.

Now I have to come to the question of the addition of lime to the slimes, and I have to apologize for a third note on the subject of float gold in slimes.

Precipitation of Slimes by Milk of Lime.—After many interesting discussions on the theory of the action of lime in precipitating slimes, it is now proved that precipitation is due to the action of soluble lime.

There has been, unfortunately, a strong opinion in favor of using lime powder in the launder, and, consequently, an objection to using lime in the form of milk of lime. My purpose, now, is to show the advantage of using lime mixed with water, and to prove that the best way to obtain a regular quantity of lime so as to obtain a complete precipitation without employing an excess is to use milk of lime.

The automatic feeder for dry lime is a very ingenious apparatus, but, in practice, is inferior to a milk of lime solution, for the following reasons:

Lime must first be crushed in some form of grinding mill.

It requires almost continual attention so as to be properly filled with lime; and sometimes, even when there is plenty of lime in the hopper, lime does not fall into the launder and the screw revolves empty. Besides, the dust is very troublesome.

The supply of lime in the launder cannot be properly regulated to the exact quantity required for a complete precipitation; therefore, to obtain a complete precipitation an excess has to be used.

Two boys are required per shift working the grinding mill, and carrying the lime to the feeders.

The advantages of using milk of lime are as follows:

By the use of an inexpensive apparatus, which can be made on any mine, milk of lime can be prepared at a regular density without any trouble by the boy in charge when he has been once shown how to do it.

The supply of the quantity of milk of lime required for the precipitation of slimes can be regulated from the slimes plant with the greatest facility at a moment's notice, by using an electric bell for signalling from the slimes plant to the boy in charge, to increase or to reduce the quantity of lime.

On account of the facility and rapidity of regulating the supply of lime in the launder, no excess of lime need be used; the precipitation is regular, and a large saving can be made in the cost of lime.

When using milk of lime, there is no necessity to crush lime through a mill, the milk-of-lime mixer being filled from the bag.

One boy only is required.

As slags and unburnt limestone are separated from the milk of lime in the mixing machine, the quality of milk of lime is much more regular than the quality of crushed lime.

The quantity of pure lime (calcium oxide, hydrated) in milk of lime depends, of course, on the quality of the lime, *i. e.*, of the proportion of carbonate of lime mixed to calcium oxide.

The annexed table gives, as an average, the quantity of lime calculated as calcium oxide, at each degree Baume from 10° B. to 30° B.

If we take 1 ounce av. = 23.35 grammes.
1 gallon = 4.54 litres.
1 cubic foot = 28.315 litres,

we can calculate the size of the apparatus required so as to contain enough lime to give the required alkalinity to slimes for a fixed time. But it would be more accurate to have a small quantity of milk of lime made with the lime to be used, say one bucket, take its density, and titrate it for calcium oxide by any of the well-known volumetric processes. As, according to the nature of limestone, and the working of the lime kiln, the quantity of calcium oxide may vary from 30% to 65% in lime, I would recommend titrating the milk of lime. The best and quickest method is to transform calcium oxide in saccharate of lime, and titrate by standard acid.

The apparatus consists of a circular tank to be partly filled with water, with a vertical axis on which are attached flat iron paddles incurved so as to move the liquid upwards. To the circular edge of the top are suspended, inside the tank, metallic baskets made of iron sheets with bottom and sides perforated.

The bottom of the baskets is to dip 2 or 3 inches in water when starting; the baskets are then filled with lime, the machine started, and the finer part of the lime falls through the holes into the liquid, and is kept in suspension, enough lime being added to raise the density to 20° B. Then, by occasionally adding water in the tank and lime in the basket, the density is easily kept quite uniform.

No cock is to be used for regulating the flow of milk of lime in the launder. The best plan is to have a square hole cut at the lower part of the tank, say 12x12, to close it by a wooden plank, and to drill through this plank several holes $\frac{1}{4}$ or $\frac{5}{16}$ inch diameter, to be closed by wooden pegs when required, so as to supply to the launder the quantity of lime required. An iron plate bent downwards behind the wooden door is to protect the flow of liquid from the agitation of the lower paddle. This is the simplest and cheapest apparatus for the purpose required.

TABLE SHOWING AMOUNT OF LIME PRESENT IN MILK OF LIME.

Baume.	*Density.*	*Calcium oxide per 1000 grammes.*	*Average grammes per 1000 c.c.*

A Cause of Irregularities in Treatment and of Errors in Assays of Slimes —When recently reading the journal of the society I noted an observation made by J. R. Williams on slimes carrying away fine particles of gold, the latter thus escaping amalgamation. It reminded me that two years ago, when experimenting with old slimes to test an apparatus patented by E. Brochon, I had much trouble, and was unable to obtain reliable and concordant results before and after the experiments, until I had devised a method of taking the assay from a part of a very large sample, say 12 to 15 A. T., specially prepared to eliminate errors due to particles of gold of different size being mixed in the slimes, and not being even distributed all over the lot.

I will describe the experiment and mode of sampling I have adopted so as to obtain a very correct analysis, despite the irregular distribution of the particles of gold in the mass.

The apparatus I had to test was unfortunately of too small a size, so that it could not be run for many hours without being blocked by an accumulation of slimes. It looked like a lot of flat boxes piled one over the other, formed alternately of amalgamated copper plates separated by an india rubber isolating frame from iron plates, both to be used as cathodes and anodes respectively. The plates were perforated at alternate ends, so that the slimes could circulate between the plates and run all through the apparatus, the distance between the parallel plates being $\frac{1}{8}$ or $\frac{5}{16}$ inch.

By a special arrangement, which it is not necessary to describe, small measured quantities of slimes entering the apparatus, and also at the exit of the apparatus, were taken at regular intervals.

I had a lot of old slimes, well mixed and sieved, weighing about 100 pounds, kept in a box, the moisture being 3.54%, 3.55%, 3 58%. I took samples for assays for different parts—top, bottom, middle, diagonal, etc. Instead of mixing all the samples in one lot I decided to analyze each sample separately, so as to see if there was any difference. The assays were made under exactly the same conditions, as well as in the subsequent experiments, litharge, charcoal and fluxes being weighed and new crucibles used. I was surprised to obtain the following results:

GOLD PER TON.

Ounces.	*Pennyweights.*	*Grains.*
0	4	9
0	3	5
0	6	0
0	3	5
0	3	2
0	2	19
0	3	10
0	2	14
0	3	0
0	4	0
Average. 0	3	13½

I could only think that the irregularities were due to some particles of larger size being irregularly distributed, even after the more careful mixing. I supposed that by taking part of the lot, mixing it with water to about seventy gallons, I would get a more regular sample, and that by running the slimes through the apparatus I would be able to detect if floating gold had been retained by the amalgamated plates—of course, no source of electricity being used in such experiment. The alternate plates of amalgamated copper and of iron were not to act as cathodes or anodes, respectively, but were only to be considered as a series of amalgamated plates over which the slimes were running in a thin film. The result has proved that part of the gold is irregularly distributed in slimes, and that this is so is shown by the fact that some years ago amalgamation was probably not so effective as it is now. No cyanide was used in the solution, but, for another purpose, about $\frac{1}{1000}$ of HCl had been added to the water. From each lot four assays have been made:

A.—Slimes before entering the apparatus.

B.—Slimes after they had gone four times through the apparatus.

C.—Slimes after they had gone six times through the apparatus.

The balance of the lot C having been lost through

* Condensed from Journal of the Chemical and Metallurgical Society of S. A.

some misunderstanding, I weighed the balance of lots A and B and put each lot in a porcelain basin, where it was moistened with water and treated with aqua regia on a water bath and left for the night; then, after being well mixed with a glass rod and an addition of carbonate of soda, each sample was dried and weighed again. From the original weight compared with the second one, a simple calculation indicates the weight which will correspond with 1 A. T. of the original sample. Under such conditions the gold is evenly distributed all over the mass.

Incidentally I would recommend a similar treatment to distribute gold in the samples taken for analysis of concentrates.

Two assays made for each lot agreed exactly, and the results were:

	Oz.	Dwts.	Grs
Gold in slimes before amalgamation....	0	4	2½
Gold in slimes after amalgamation.	0	3	13½

So without any chemical treatment 13.2% of the gold in original slimes was recovered.

To conclude: Gold is very irregularly distributed (I do not say in all slimes, which may vary with the different reefs; I say only in some slimes).

Some particles of gold are not so fine as the others, and in such case we might ask if, the bigger particles, being heavier and settling first, are or are not entirely dissolved by the extremely dilute cyanide solution, since, as soon as they begin to settle, they are protected by the heavier slimes from the action of the solution. Besides, being in the bottom of the tank, there is a possibility of escaping sampling. If such is the case, the assay of residues is lower than it should be, so the percentage of extraction seems higher than it really is.

On the question of assays of slimes we have also to conclude that, to make the assay quite accurate, it is to be made from a lot of 12 to 15 A.T. treated as I have explained, so as to have the gold dissolved and distributed all over the sample.

I would recommend the following method of preparing samples of slimes for analysis (original sample before treatment):

Use a small experimental filter press; filter the slimes through the press, after the pulp has been well mixed, and make two, three or more cakes, according to the volumes of the original sample. The size of the cake is 17¾ centimeters diameter (7 inches) and the thickness 1 centimeter, 2 centimeters or 3 centimeters, according to the frame being used (0.394 inch, 0.798 inch or 1.192 inches). The larger cakes when fresh weigh 1 kilo 442 grammes, when dry 1 kilo 030 grammes; water lost, 0.412 kilo, or 28.57%. Now, from each fresh cake two opposite triangular parts are cut, and this lot is well mixed with water to a pulp and sent again through the filter press, until only one cake is obtained. From this cake, being a good average of the lot, and weighing, when dry, nearly 35 A. T. for the larger frame, cut triangular opposite parts, so as to get nearly half of the cakes, 16 to 17 A. T. Dry it, take the weight and treat as previously described, by aqua regia, etc., to get the final samples for assays.

For slimes after treatment, residue samples, containing dissolved gold, weigh first 100 grammes of the pulp and dry it, so as to get per cent solution and per cent residue slimes. Now send the full lot of the sample through the filter press, keep a sample of the clear solution for determination of dissolved gold, and prepare the cakes through the filter press as above described, until the last one is obtained; then, through this cake, by the special pump of the washing apparatus, force a few bottles of water so as to remove all soluble gold, and treat the washed cake as previously described for undissolved gold.

Mining Definitions.

One of the push gives the following definitions of mining terms:

A prospector—A man who has a hole in the ground and is the biggest liar in town.

A proposition man—One who wears laced boots and corduroy clothes and never pays his board bill.

A mining expert—A man who can talk about formations, ramifications, stratifications, dykes, zanes, dips, spurs, angles, teligtites, oozites, seddemites and all the other ites and tites; can see a mile into mother earth and invariably condemns the country.

An expert miner—A fellow who loafs around town looking for a job as superintendent of a property, but would be a foreman if he can't be superintendent; one who worked on the Comstock in '70, and has been idle ever since.

A "49er"—A man who came to the coast in the "fall of '49 or spring of '50," and knows where there are diggings that will pay $1.50 to the pan, and is going back there just as soon as spring comes.

A mining reporter—A man who wants you to subscribe for his paper, wants to write up your property, and wants you to take him out in the best buggy in town, smokes your best cigars and borrows $5.

A mine promoter—A man who has unlimited capital behind him, but not any in front of him; his watch is in soak.

A tenderfoot—A "Willie boy" just out from the East. Carries a small arsenal with him, goes out prospecting with a shotgun and a fishing rod, buys a salted claim and gets money from mother to come home in the fall.

An amalgamator—A man who wears long fingernails, draws $5 a shift and deposits $10 in the bank every day, if the ore is low grade, and more in proportion.

"A local mill man of note"—One who has been on the eve of starting for South Africa or some other far off region for seven years, to take charge of the construction of a 1000-stamp mill for a London syndicate; a man who has been positively known to have constructed a sawmill.

An assayer—A man who charges you $1.50 for throwing your samples out of the back door and writing a certificate.

A mining engineer—One who makes funny figures on blazed stumps and charges a big price.—Baker City (Or.) Democrat.

Across the Pitch Versus Up the Pitch.*

By O. E. S. WHITESIDE, Anthracite, N. W. T.

The above title tersely directs your attention to a comparison of the getting of coal from breasts driven across the pitch, nearly in the direction of the strike, and parallel with the gangway, with the same operation in breasts at right angles to the strike, or straight up the pitch, under a few of the conditions that obtain in pitching seams.

In the Cretaceous measures at Anthracite and Canmore the pitch may be said to vary from 30° to 50°, although at some parts worked the seam is flat and at others pitches 90° from the horizontal, while anticlinals and synclinals of coal are no uncommon thing.

Slopes are sunk to the depth desired on the seam, and in most cases it is necessary to do considerable grading to obtain a 300-foot slope without a knuckle or roof roller. Gangways are then started to the right and left, their course being directed by the proper gradient and the varying strike of the seam. The method adopted for lowering the coal to the gangway is, in the main, by means of chutes, although back balances or self-acting planes are resorted to in special cases. On the upper levels, where the "up-the-pitch" system of work had been adopted, gangways were driven 12 feet wide and chutes 8 feet in width were started up the pitch, leaving gangway stumps 32 feet along the gangway by 20 feet up the pitch. These chutes were then widened to 20 feet for the remainder of the way up, leaving pillars 20 feet wide, through which crosscuts 8 feet wide were driven at intervals for ventilation. In this manner the coal was worked towards the boundary, the pillars being left to pull on the way back.

After working this system for some time, it was deemed necessary, if possible, to adopt some other which would lend itself more readily to the cleaning of the coal within the mine, and thereby lessen the cost of handling and transportation.

In a paper on "Subsidence Caused by Colliery Workings," by Joseph Dickinson, F. G. S., the author, in speaking of pillars left for support, says: "Pillars for horizontal seams may be either square or oblong; but for inclined seams, oblong pillars lengthways between rise and dip are preferred, especially where well-defined cleavage or slips run level course."

This "up-the-pitch" system then left the preferred supports and the pillars were not so liable to be over-ridden and run out on a steep pitch as oblong pillars with their length across the pitch, especially where the coal is full of slips, and more especially if there is a well-defined cleavage in the direction of the strike. Breast cars were not needed; the coal fell to the chute without handling, and, if the chutes were kept full, neglecting the sizes in which it was mined, the first ought to have been delivered to the gangway, with a minimum of fall and breakage for chute delivery.

The other system which made it an easy matter to separate the rock and other refuse from the coal at the working face, with ample room to gob the same, made it necessary that the length of the oblong pillars should be in the direction of the strike. Working the coal in this manner across the pitch requires less labor and lumber for chutes; and, as it is necessary to have a wall to separate the gob from the roadway, the ventilation of the face is accomplished by the same process, and the ordinance requires the air to be kept within 12 feet of the face. This method reduces the work more nearly to that necessary on a flat seam, and consequently does not require the skilled labor necessary for "up-the-pitch" work. This matter of skilled labor probably counts for more with us than in some older districts, because laborers from the ranching country are always plentiful, while miners are very often scarce, especially those skilled at working up a steep pitch.

With regard to the strength of the pillars, a defined cleavage was not a marked feature of any of the seams which we have worked, consequently the change of system did not affect us as it might have some of the pitching seams of Pennsylvania.

In the "across-the-pitch" system adopted, narrow work was in some cases dispensed with where the seams were not close together and the coal without a well-defined cleavage. Here the gangways were driven 20 feet wide. Chutes 20 feet in width were started up the pitch, with pillars 150 feet long between them, and every 30 or 40 feet up the pitch breasts 20 feet wide were worked across the pitch to the inside chute. In this way oblong pillars were blocked out with their length across the pitch—150 feet long and 30 or 40 feet wide. In all breasts across the pitch and most gangways the road is carried on the low side and the gob and return air on the high side.

The seams worked are from 5 to 10 feet in thickness and a row of props is carried close above the track. These props are lagged. The coal is shoveled into the cars and the refuse and rock stored above, and in most cases there is enough to completely cover the props and make a good air course.

Two seams lying rather close together gave some trouble, partly on account of the measures between thinning out locally. Before starting work on these seams the rule was laid down that all breasts up the pitch on the lower seam should be driven by sights directly under those on the seam above and those across the pitch directly under those above, in the direction in which a prop should be placed. It was also decided that these places should first be driven on the overlying seam and followed later by those on the lower one. This latter rule was not strictly lived up to, owing to the intervention of faults and the demands of the market for some few months after the commencement of this work, but no trouble was experienced for a considerable time after the pillars had been blocked. Finally the floor of the upper seam commenced heaving and the pillars started to run, so we slowed up work on the lower seam and started pulling the pillars of the one above before they had time to run out. In a great many cases where one breast had broken through into another, we found the thickness of the measure between to be only 6 feet and in one case they actually run together, whereas the thickness we had previously was 14 to 20 feet.

From now on we intend to push the solid work of the overlying seams and immediately follow up by pulling the pillars, and then, after the removal of everything except the stumps, to mine the lower seam by a similar process.

Considerable might be said as regards the waste in mining and handling the coal in these two systems, also concerning the pulling of pillars.

*Transactions Canadian Mining Institute.

State and Federal Mining Law.

TO THE EDITOR:—In reply to the current question as to whether a State law may require the performance of work on a mining claim at any time within the calendar year during which such claim is located, I answer "Yes."

Under Sec. 2322, Rev. Stats. U. S., it is only "so long as they comply with the laws of the United States, *and with State, Territorial and local regulations not in conflict with the laws of the United States*, that locators are entitled to the possession and other enjoyment of their locations.

Sec. 2324, Rev. Stats. U. S., provides that "The miners of each mining district *may make regulations* not in conflict with the laws of the United States, or with the laws of the State or Territory in which the district is situated, *governing the location, manner of recording, amount of work necessary to hold possession of a mining claim*, subject to the following requirements: The location must be distinctly marked on the ground so that its boundaries can be readily traced. All records of mining claims hereafter made shall contain the name or names of the locators, the date of location, and such a description of the claim or claims located by reference to some natural object or permanent monument as will identify the claim. On each claim located after the tenth day of May, eighteen hundred and seventy-two, and until a patent has been issued therefor, not less than one hundred dollars' worth of labor shall be performed or improvements made during each year."

An Act of Congress approved January 22, 1880, provides "that the period within which the work required to be done annually on all unpatented mineral claims shall commence on the first day of January, succeeding the date of location of such claim, and this section shall apply to all claims located since the tenth day of May, Anno Domini eighteen hundred and seventy-two."

It is manifestly the intention of said Sec. 2324 to prescribe the minimum requirements for locating, recording and working a claim. But it is equally manifest from the language of the section itself that additional requirements may be established by either State, Territorial or district laws.

For instance, the Federal statute does not require any record of a mining claim; but a record may be required by State, Territorial or district regulations, and when so required such record must include the details set forth in said Sec. 2324.

It is clear that no valid regulation can be made, either by a State, a Territory or a district, which will enable the locator to hold a claim by performing

less than $100 worth of work during any calendar year; but Sec. 2324 permits even a mining district to regulate the "amount of work necessary to hold possession of a mining claim."

How, then, can a State, a Territory or a mining district make a regulation "governing" the "amount of work necessary to hold possession of a mining claim," *except by requiring the performance of more than $100 worth of work during each year?*

And so as to the requirements for the making of a location. The Federal statute does not require the doing of any work on the claim as part of the making a location. But such work may be required by State, Territorial or district regulations.

In the Rocky Mountain States and Territories this work is called "location work," and there the statutes requiring it have been upheld invariably.

I am aware of the decision in Williams & Kellinger vs. Winthrop Mining Co., 60 Cal., 631, to the effect that local regulations cannot require "that work shall be done every sixty days on the claim."

But the Supreme Court of the United States has permanently settled the main question now under discussion by its decision in Belk vs. Meagher, 104 U. S., 284, where it is said:

"The right to the possession comes only from a valid location. Consequently, if there is no location, there can be no possession under it. Location does not, necessarily, follow from possession, but possession from location. A location is not made by taking possession alone, but *by working on the ground, recording and doing whatever else is required* for that purpose by the Acts of Congress *and the local laws and regulations.*"

This language has formed the basis of numerous decisions, notably in Colorado and Montana.

I may profitably repeat that neither "working on the ground" nor "recording" is anywhere required by the Federal statutes in order to complete a location. Yet the United States Supreme Court says, in the language just quoted, that, where the local laws or regulations require that the acts of location shall include "working on the ground" and "recording," both are necessary to the making of a valid location.

In the present condition of the mining statutes of California my opinion is that the only perfectly safe course for a locator in this State is to comply with the California statute of 1897, as well as with the requirements of the United States statutes.

JOHN M. WRIGHT.

San Francisco, Cal., Aug. 23rd, '99.

The Buffalo Hump District, Idaho.

Herewith is presented a view of Buffalo Hump, Idaho, from a photograph taken by our special correspondent for this article last month. The camp is usually reached from Grangeville and is about fifty miles distant therefrom. About thirty miles of this distance is over a wagon road, the remaining twenty miles being by trail. Grangeville is reached either from Weiser, on the Oregon Short Line, or from Lewiston, on the Northern Pacific and O. R. & N.

BUFFALO HUMP, IDAHO, LOOKING WEST FROM CONCORD TOWNSITE.

With all the adverse reports from persons returning from the Hump country, there is unmistakable evidence of excellent surface showings in the region thus far prospected, and the developments seem to bear out this evidence.

The Big Buffalo, owned by Bert Rigley and the heirs of Charles Robinson, is at present tied up by litigation, thereby retarding development that otherwise might be made. The development on this property is limited to a shaft 70 feet deep, a 40-foot crosscut and 100 feet of drifting. This work discloses a ledge 40 feet wide and 250 feet long. The ore averages from $15 to $20 per ton.

The Cameron-Norman syndicate are developing the Monte Cristo group, which they hold under option. They have uncovered 5 feet of ore which assays an average of $25 per ton. Further development by a crosscut is in progress. The same parties are also developing the Fortune, which shows a strong vein on the surface, averaging about 7 feet in width, giving reported assay values of from $10 to $30 per ton.

The Boston-Buffalo-Idaho Con. Co. are developing the Concord group. A shaft has been sunk 46 feet in ore of stated value of $20 per ton. They also have 200 acres platted for a townsite.

Clark & Sweeney of Spokane are developing the Cracker Jack and Jumbo, the two being four miles apart. Their present work consists of a tunnel 150 feet long, which cuts the ledge of ore at 100 feet depth, a second tunnel, 350 feet in length, cutting the vein at 225 feet depth. The face of the tunnel shows 12 feet of ore, which is asserted to show assay values of from $6 to $150 per ton.

Twelve samples from the St. Louis, according to assayers' certificates exhibited, averaged $115.45 per ton. This property is one and one-half miles south of the Big Buffalo and is under option to Young & Turner of Spokane. The vein uncovered here is about 8 feet wide. The assays above referred to came from six surface cuts, covering 600 feet in length on the vein.

Out of 250 assays made by Buffalo Hump assayers from various properties in the district, it is asserted the average value was $26.90 per ton.

The ores of the district generally are a sulphide of iron and copper, with values in gold, silver, lead and copper. Much of the lead occurs as galena.

The altitude of Buffalo Hump camp is 8800 feet above sea level. Much of the distance by trail is extremely rugged, mountainous and picturesque.

The Lucknow, N. S. W., Gold Field.*

By A. R. CANNING.

Necessarily the sampling for market purposes of such rich stuff as that obtained from the "firsts" and also of the higher grade of concentrates has to be carried out with great care. For some time the custom was to run all the dried ore into a small hopper leading to a short down pipe which was subdivided many times until one-sixteenth of the bulk fell into a receptacle, out of which a sample was taken, the rest falling into a large hopper, from which the bags or casks were filled. Six check assays were made of the sample thus obtained, and the mean of these was taken. Later on it was found that, however dry the ore was, and however carefully mixed, some of the richer particles adhered to one another, forming small lumps, and that these seldom passed through into the sample box; the assays, therefore, underestimated the true value of the parcels. In place of this sampler, a gauge like an elongated cheese tester is now used, and by this cores can be obtained from the filled bags which give far more reliable returns.

With regard to the effect on the copper plates of antimony contained in the stone sent to the mill, a few interesting points may be noted. This metal is not found to sicken the plates to any appreciable extent, but the amalgam collected when much antimony is being put through is low in quality, averaging only about 33%, instead of 45% to 47%, bullion gained from the usual amalgam. When low-grade amalgam is obtained it is generally cleaned, the dross being floated off; this latter is found to contain about 17% of high-grade bullion, which is recovered by roasting the dross before retorting.

A curious specimen, consisting of a piece of stone carrying about 75% of pure antimony, had got among the "firsts" and was found in the mortar box after a parcel had been put through. It showed the outside faces to have taken up quicksilver and formed an antimony amalgam; two small pieces of gold amalgam were seen adhering to the sides of this stone. On one occasion, when a somewhat large patch of antimony had been struck, some tons of it were dressed to yield about 70% metallic antimony. No market, however, was found for it; either the antimony or the gold contents were negotiable, but not the two. The gold running to thirty-five ounces to the ton, the antimony was consequently sacrificed, and the stone was mixed in small quantities with the ordinary milling dirt and put through the battery, and the gold extracted in the ordinary way.

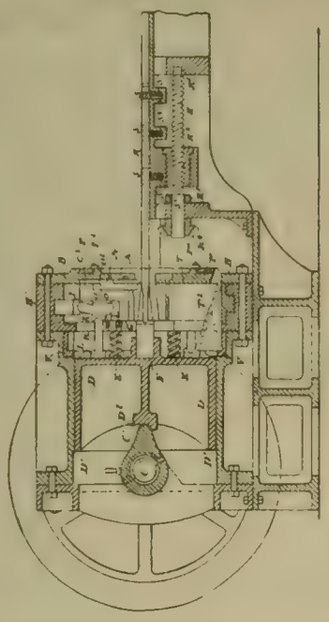
The many interesting characteristics associated with the Lucknow gold fields tend to increase rather than to diminish the difficulty of writing a paper on the subject. Geological, mineralogical, mining and milling descriptions have had to be given, and these in dealing with characteristics, many of which either have not been or have been but rarely met with elsewhere. There are points in connection with this field that claim the attention of each branch of the mining and metallurgical professions, and with so far-reaching an interest the writer cannot expect, nor does he hope, to escape criticism; such criticism can hardly fail to be instructive.

In dealing with the geological features the writer has endeavored to give a full and clear description of each point that has been noted in the workings. In facing a problem which is undoubtedly a difficult one and capable of inviting different solutions, certain points, that to one may seem trivial, to another may appear to supply circumstantial evidence towards the advancement of some particular theory. The all-important question as to how the gold and auriferous pyrites became deposited in their present position raises the consideration of many points. What inference is to be drawn from the gold being found in shoots of calcite? Does the absence of gold in the quartz reefs at a distance from the joint suggest that a leaching process took place, which concentrated the finely distributed particles of gold into rich shoots at or near the line of contact; or does the presence of antimony and arsenic at once mark the deposits as being of deep-seated origin? Again, was the deposition of the gold contemporaneous with or subsequent to the earth rendings that resulted in the formation of the serpentine? Mention has been made of an important feature at the northwest end of the ground, where the two diorites close in, only leaving a narrow band of soft "dig" intervening; how that, in spite of new reefs being struck here, carrying all the other characteristics of the pay veins, no gold has been found in them. Also, of certain veins, these, too, at the northwest end of the ground, carrying gold downwards until the diorites close in, and then become barren of gold. It would seem quite possible that serpentine will be found to widen out and again fill the space between the diorite and the veins recommence to carry gold; but, nevertheless, the failure of the pay shoots when serpentine is absent would appear to put beyond doubt the contention that the same forces that assisted the formation of the serpentine had much to do with the deposition of the gold. The final question, one of great interest alike to the geologist and to the investor, is, of course, what are the chances of continuation in depth, and this cannot be answered until a satisfactory solution to the above points have been arrived at, or the energetic prospecting now being carried on at the mines give actual proof one way or the other.

Looked at from a mining point of view, it will be seen that unusual features have presented themselves, preventing the adoption of several accepted rules in working ground, or necessitating considerable modifications to them. These have not been dealt with in detail, because it has appeared to the author that conditions of an exactly similar nature are unlikely to be met with again, and that their record would render but little service. With such extensive workings (extensive if compared with the depth reached and with the small output of milling ore), and with men employed in faces remote from the shafts, everything is done to prevent time being lost. A general principle has been adopted. Thus, unless under unusual circumstances, miners do not lay their own rails, fix on air pipes, put in timber, etc. Plate and pipe layers, timber men, and their assistants are maintained, and they have to fly around, keeping the work up to date. In the case of the latter work, timber hitches are marked out where necessary, and afternoon and night shifts cut them out ready for the timber men to work on during day shift. Nothing is allowed to hinder the actual work in the face. Contracts are let where possible, but the changes in the direction and in the class of rock to be traversed are so constant that the setting of piece work is difficult and cannot be resorted to as frequently as desired.

Telephone communication has been used during the last twelve months, connecting the two ends of the mine and the manager's room. This has been of great service as a means of saving time and labor, and by allowing sudden changes in the country to be reported, so that unnecessary or ill-directed work can be prevented. No accidents to life or limb have had to be reported during the past three and a half years, and, though no comparison can be made with the working of dangerous mines, at the same time it may be useful, especially to the students of this institute, to mention that this satisfactory record is attributed to the strictness in punishing men for carelessness without waiting for an accident. A single example of a miner dismissed for working under baulked ground, instead of first taking it down, produces an excellent result, and the same may be said with regard to punishment for reckless handling of explosives, rushing of cages, etc.

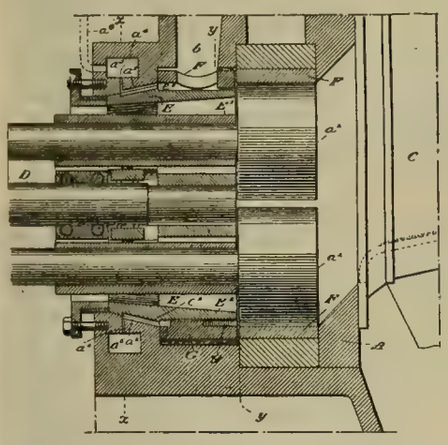
The difficulty of preventing the stealing of rich ore is ever present, and not only is a very large sum of money annually expended endeavoring to prevent loss by this means, but each move made in the mine and each appointment of foremen is influenced by this question. Precautions taken in one direction only appear to divert the danger into another. Changing rooms, of course, exist at each shaft, but nothing can prevent a certain amount of leakage through this channel. Collusion between several men was at one time very prevalent, but since the strike of 1897 this danger has been eradicated. Mineralogists and milling men can hardly fail to find certain unusual and interesting features in connection with the auriferous arsenical pyrites and antimony.



*Condensed from a paper read before the Institution of Mining and Metallurgy.

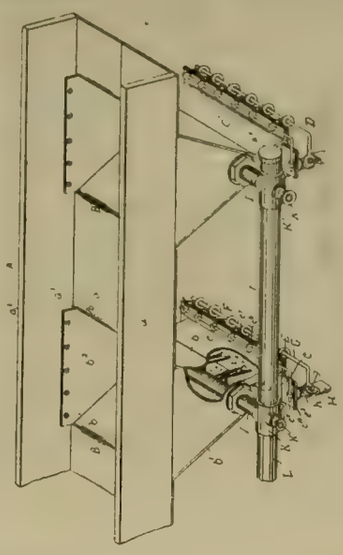
Latest Mining and Metallurgical Patents.

Patents Issued Aug. 22, 1899.



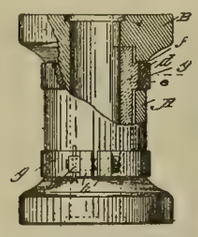
Specially Reported for the MINING AND SCIENTIFIC PRESS.

MACHINE FOR FORGING AND SHARPENING ROCK DRILLS.—No. 631,281; W. Daly, Johannesburg, South African Republic.



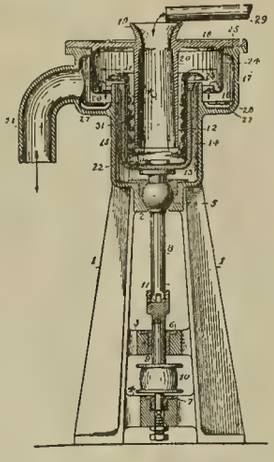
An improved drill sharpening and forging machine consisting in combination of a rotary shaft *A* provided with an eccentrically moving member operating a horizontal sliding block *D* provided with a sharpening die *F* formed with a cress to sharpen the particular shape of bit required, the series of forming hammers sliding in guides *G'* formed in the circular front plate and working toward a common center and adapted to form the shank of the bit operated from the main sliding block *D* through the toggle links *K K'*, the tension springs *E E* and *G² G²* for maintaining the parts in their relative positions, the cutters *N* operated from the sliding hammers *G* and controlled by the wedges *O* connected through the links *P'* to an adjustable annular plate, the adjustable jaws *T* to determine the size of the web of the drill working in guides *T'* formed in front of the circular plate *V* provided with circumferential inclines and the holding device consisting of a table adapted to the front of the machine having a sliding top *R* regulated and controlled by the screw worm *R'* and furnished with the spring stops *S S*.

PULVERIZING MACHINE.—No. 631,291; G. Frisbee, Philadelphia, Pa.



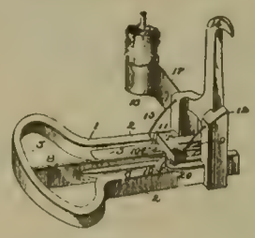
In a pulverizing machine, a die, a crushing roller, a rotatable disk back of die and closing one end of the pulverizing chamber against the discharge of pulverized material, grooves formed in the periphery of disk, an external casing around the pulverizing chamber and disk, grooves on the interior surface of external casing adjacent to the grooves in the disk, the former grooves being arranged at an angle relatively to the latter, whereby a current is created. In a crushing or pulverizing machine, a ring die, crushing rollers, a rotatable disk at one end of the pulverizing chamber, a series of obliquely arranged grooves on the periphery thereof, grooves being closed at one end, and a series of grooves in a stationary part adjacent to the first-mentioned grooves but arranged at a relatively different angle. The rotatable disk having inclined-faced projections thereon adjacent to its outer edge and directed toward the axis of rotation of disk, with a spirally grooved stationary ring surrounding disk, grooved portion of the latter being out of the path of movement of projections.

ORE CONCENTRATOR.—No. 631,411; E. C. Sooy, Kansas City, Mo.



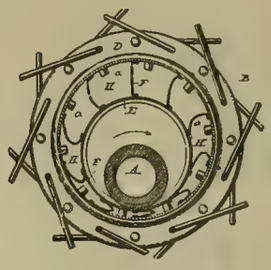
A receptacle for ores having sides and outwardly extended flanges upon the lower portions of sides, a detachable bottom to receptacle, a hinged connection of one side of bottom with one side of receptacle, the free edge of bottom and the adjacent flange on receptacle having openings registering with each other, a clamping nut opposite each of the several openings having a ring integral with nut, an eyebolt in each opening within its respective nut, a link connecting one of clamping nuts with another, and a separate link connecting one eyebolt with another, and a locking device connected with each link.

TAPPET FOR STAMPING MILLS.—No. 631,535; G. W. Waitt, San Francisco, Cal.



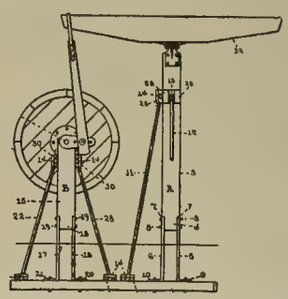
A tappet having an interior chamber or recess in its wall, and a groove around it with an opening from the recess to the groove, a gib having a stud or boss projecting into the groove, a band in the groove and mechanism for drawing upon the band and causing it to press upon the gib, the parts being constructed and combined. The combination with the sleeve of the tappet having recesses therein, a two-part hinged band, a gib arranged in each recess, one near each of the free ends of the band, sleeve having openings from the recesses through which the band and gibs are designed to contact, and means for drawing the parts of band together.

MINERAL EXTRACTING MACHINE.—No. 631,680; K. Staahlgren, Salinas, Cal.



In a centrifugal mineral extractor, in combination, a stationary cylindrical vessel, provided with an annular outer chamber surrounding the same, a cover for vessel, having a central receiving nozzle and depending cylindrical tube concentric with stationary cylindrical vessel, an annular removable pan (*27*) in the bottom of annular outer chamber, an annular depending curtain (*24*) having inturned flanges (*26*), a revoluble cylindrical vessel within stationary vessel and concentric therewith, means for rotating revoluble vessel on its true axis of mass, and a removable thin metal lining, outturned at top, within revoluble vessel.

COMBINED KNIFE AND CANDLESTICK.—No. 631,270; A. Bernier, Victor, Colo.



A device of the class described comprising a handle, the pivoted parts mounted within the handle, a slide arranged to lock the pivoted parts in their folded and extended positions, a frame mounted on the handle and carrying a candle holder, and a means for detachably connecting the frame and the slide, whereby both parts are held in position. A blade or device arranged adjacent to the guide piece, and a slide mounted on the guide piece and having portions adapted to engage the blade or device.

AIR COMPRESSOR.—No. 631,701; C. F. Du Bois, Denver, Colo.

In an air compressor, the combination of a pair of disks, eccentrically disposed cylinders therebetween, and fitted air tightly thereagainst, and means for rotating the cylinders; with collapsible partitions between the cylinders and the disks, whereby contractible and expansible air compressing chambers are formed between the cylinders and disks, the inner cylinder having sliding airtight joints with the disks and both cylinders being eccentric in relation to each other during the rotation thereof, whereby the air chambers are successively reduced in cubical capacity, as they pass the point of closest approximation of the cylinders; the eccentric displacement of the cylinders being produced by weight applied to one cylinder; and means for collecting the compressed air from the several chambers.

OIL OR ARTESIAN WELL DRILLING AND PUMPING RIG.—No. 631,504; C. C. Howell, Bradford, Pa.

In an oil and artesian well rig, the combination with the embedded main sill and subsill, of the samson post consisting of a timber of rectangular form provided with a tongue, and the iron plates provided with foot pieces, and the jack posts consisting of one timber each of rectangular form provided with a tongue, and the plates provided with foot pieces secured to the embedded main sill and further provided with the iron braces; the front jack post consisting of a timber of rectangular form provided at its lower end with a tongue, and the plates provided with foot pieces secured to the embedded main sill, and further provided with the iron braces; the back jack post consisting of a timber of rectangular form provided at its lower end with a tongue, and the plates provided with foot pieces secured to the embedded subsill, and further provided with the iron braces, the embedded main sill and the embedded subsill.

Measuring Gas and Liquid Fuel.

Wherever gas is used for heating purposes its heating value is suited as a standard for measuring the economical value and to fix the cost. The knowledge of the heating value is of importance, and the easy determination of the same desirable, as the use of gaseous fuel is increasing. Thirty per cent of the illuminating gas supplied by gas works is used now for heating purposes, cooking, warming, gas engines, etc.

The calorimeter herewith illustrated, while not inferior in exactness to the most scientific instrument, is simple to handle, requiring little time for taking a measurement, and may be attended to by an inexperienced person. It has the valuable property, inherent in no other calorimeter, of enabling a continuous determination of the heating value to be made, and of therefore continuously showing the fluctuations of the heating value. Besides determining the economical value of a heating gas, the calorimeter may be employed as a useful instrument in many other cases, as it gives, by means of the heating value, a number of other indications of all kinds, taken either directly or indirectly therefrom, in the same way as, for instance, the indicator of a steam engine affords, besides the amount of work performed, indications as to steam distribution, leakage in the steam pipes, etc. The calorimeter can, therefore, serve for controlling the mode of working of the gas producer, and of the separate periods of working this apparatus (illuminant gas, generator gas, or the like producer; coke ovens, blast furnaces, etc.); further, for fixing the working degree of the apparatus for heating purposes or power production. Especially in the testing of gas motors this calorimeter is of great importance.

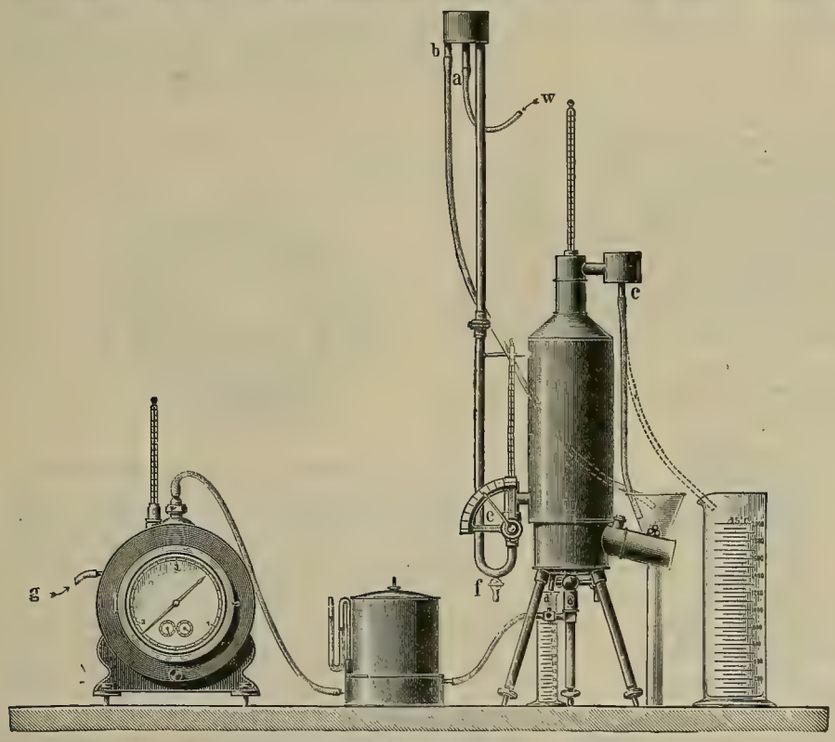


FIG. 1.—THE JUNKERS GAS CALORIMETER.

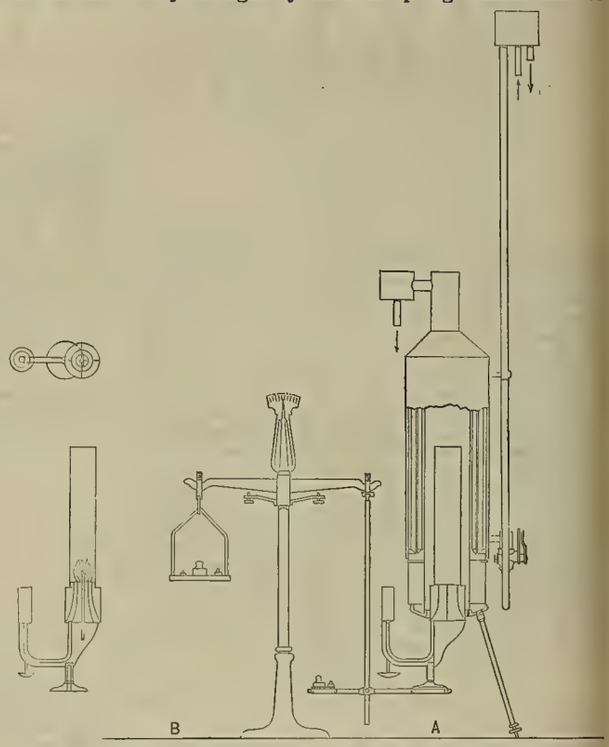

FIG. 2.—JUNKERS' CALORIMETER FOR LIQUID FUELS.

The mere determining of the consumption of gas is not decisive for the value of a motor, as the heating value of illuminating gas from the same gas fluctuates between wider limits even than does the consumption of gas of equal value by different patterns of motors. The importance of the instrument has been recognized by practical men.

The determination of the heating value of combustible gases takes place in the calorimeter by a state of permanency being established in the same, in which the heat, developed from a constantly burning flame, is entirely transmitted to an evenly flowing stream of water.

For making use of the calorimeter, the following adjuncts are necessary: 1. A water pipe capable of supplying from one to three liters per minute. 2. Standard thermometers from 0° up to 50° C. and divided into $\frac{1}{10}$ degrees for the water inlet and outlet, and an ordinary thermometer up to 30° or 50° for the waste gases. 3. A correct gas meter, with a large dial and thermometer. 4. A large measuring vessel for exactly determining a quantity of water, and also another small one for 50 to 100 cubic centimeters. 5. India rubber tubing for conveying water and gas. Stoppers for holding the thermometers. 6. A pressure regulator for the inflowing gas, because the pressure in the main fluctuates.

The calorimeter is placed in such a way that both the thermometers for the water inlet and outlet may be easily observed. The vent for the escape of the waste gas must be protected against the inrush of air. The gas meter is so arranged that the index may be observed while the water, running from the calorimeter, is collected for the purpose of measuring, so that all the readings may be taken by one person.

The center nozzle *a* is connected with the water main by means of india rubber tubing. The nozzle *b* is provided with an overflow pipe, which must, however, be arranged so that it can be seen that the overflow is really taking place during the measuring (such a device may be formed by inserting a short glass tube in the rubber pipe). The nozzle *c*, for discharging the water from the calorimeter, is connected with the tubing in such a way that the water discharged may be easily, and without splashing, conveyed into the graduated glass cylinder.

A glass is placed under the small tube *d*, in order to catch the water of condensation.

After the thermometers have been placed in position, the regulating cock *e* is opened (the pointer of of the dial being in a vertical position) and the calorimeter is filled until the water runs from *c*.

In this way the freedom from leakage of the inner part of the apparatus can be ascertained if there is no leakage from the small pipe *d*.

Professor Junkers has invented additional apparatus to also determine the caloric values of liquid fuels such as petroleum, kerosene, naphtha, turpentine, alcohol, oils, etc.

The calorimeter used for these tests is identical with the one shown in Fig. 1. The principal part of Fig. 1, the gasometer and pressure regulator, are dispensed with. In their place a specially constructed balance is used which carries on one side the burner consuming the liquid fuel, in the other pan the weights to determine the amount of fuel consumed.

Further detailed technical information regarding these calorimeters can be had on application to Eimer & Amend, 205–211 Third avenue, New York City.

Some Experiences of a Working Miner.

NUMBER XXX.

Written for the MINING AND SCIENTIFIC PRESS.

The value of a technical education is never more useful in any pursuit in life than in mining. I have met and talked with some thoroughly educated mining men in my travels. I recall one of them now—Prof. D——. Some men who have a finished education do not possess the happy faculty of imparting to others the knowledge which they themselves have absorbed. Not so the professor, however, for he was just bursting with information and it would bubble out spontaneously. Why, I have known the professor to take a piece of the most ordinary looking rock in his hand, glance at it casually and describe its manner of formation, its position with relation to a vein, whether from foot or hanging wall, and he could even tell the width and character of the vein and the value of the ore. I never could understand how he could do this, but it seemed as easy to the professor as reading out of a book. As a matter of course there are always those who do not appreciate the value of such talents as the professor possessed in such an eminent degree, and, being envious, ask absurd questions in an endeavor to lead the educated party into some ridiculous error. One day a miner handed the professor a dark, smooth, peculiar looking ball and asked his opinion without volunteering any information concerning it. The professor put on his glasses, "hefted" the ball, turned it over and over in his hand and said, "Well! This is interesting. I was not aware that these concretionary formations occurred in this section, but it is most unmistakably a concretion from the Cretaceous. These spheres are the result of a process of accumulation of atoms of ferrous oxide in the sandstones of the Cretaceous and sometimes are of great size. It is a very interesting specimen."

"Yes," assented the miner, "it sure is that." As he said this he deliberately opened his pocket knife and proceeded to cut the ball into halves, and added, "You see, professor, this is a ball of hair out of the stomach of a Cretaceous cow."

This young man had none of that respect for old age which is considered a virtue. Do not imagine that the professor was without a following. He had large capital to back his judgment and he spent a great deal of money for his company, though I never heard of his making any for them. Among his other exploits he constructed a flume in a canyon where the greater portion of the year was only a small stream and where in winter and spring was a rushing, roaring torrent which swept out the flumes and ditches without delay. He built a mill directly in the mouth of a tributary canyon, and it too was badly damaged by the first spring freshet that occurred after it was erected. Several experiments of this nature were made and each resulted disastrously, still Prof. D—— had a reputation, such as it was. It has often occurred to me that if he had had a few grains of common sense with his technical education he might have made fewer blunders if no successes.

* * *

I happened along at the P—— M—— mill one day and found the man in charge reading a story paper while the mill was clattering merrily away crushing ore worth $140 per ton. The first thing that caught my eye was the picturesque islands of sand which had accumulated on the apron plates, covering three-fourths of their surface, while a goodly portion of the plate not covered by sand had a lovely golden hue. The mill man greeted me cheerfully enough and seemed satisfied with himself and all the world. I pointed to the plates. He nodded, and bawled into my ear "Short of water." I suggested shutting down one battery and employing all the available water in the other. He thought it would be too expensive, as it would reduce capacity one-half, and assured me he was catching most of the gold inside of the mortars. I didn't agree with him and offered to prove it by panning the tailings. He did not hail my proposal with the delight he might have shown, but still made no serious objection. Pan tests showed a good deal of quicksilver passing off into the tailings and also little particles of hard amalgam. He was, fortunately, getting about 50% inside of the mortars. He was later directed by the owners to shut down one battery, and several tons of tailings were shoveled up and put through the mill a second time and they were found to pay as well as the ore run previously. Some men in charge of quartz mills should be driving a sprinkling cart, but perhaps they would not know when the tank was empty.

MINER.

Mining Summary.

ARIZONA.

COCHISE COUNTY.

Globe *Silver Belt*: It is reported that one company will buy the several mining properties in Tombstone and provide a pumping plant to unwater the mines. It is now twelve years since operations ceased, owing to the destruction of the pumps by fire, and Tombstone has since steadily declined.

GRAHAM COUNTY.

Graham *Guardian*: The Horsehoe mine, located in the Lone Star mining district, is ten miles in a northeasterly direction from Safford. It shows on the surface in the shape of a horseshoe. The ledge is a circle, except 40 feet on the west, which is covered with the surface soil. It is 750 feet around this circle. The ledge is from 4½ to 6 feet across, averaging 6% to 12% copper and carrying some gold and silver. Four shafts have been sunk on it in a space of 500 feet. The deepest is 35 feet.

MOJAVE COUNTY.

Kingman *Miner*: W. E. Ewing, of the Sheeptrail mines, reports the 20-stamp mill ready to crush ore. The bins and chutes are full of ore at the mines. A tunnel is being driven into the mine from the valley and is now near the vein. All ore will be handled through the tunnel. At the mill the pulp will run over plates and concentrators and the tailings cyanided.

PIMA COUNTY.

Arizona *Star*: F. McMasters of Los Angeles bought the Tres Amigos property a few days ago for $40,000. Shafts have been sunk and tunnels driven. A small stamp mill is running night and day, eight tons of ore being handled daily. No ore is put through the mill that runs less than $25 per ton. Twenty men are employed. Beside the increase in the capacity of the mill, Mr. McMasters is figuring on placing a cyanide plant on the property to handle the tailings. —— The Golden Eagle mines, belonging to Mr. McDonald, are making a good showing.

YAVAPAI COUNTY.

The Hillside mine, fifty-five miles west of Prescott, is one of the most valuable mining properties in Arizona, but has been idle for several years owing to litigation. The vein was discovered by J. Lawler. The croppings were limited to a foot in width and were not exposed over 10 feet in length. The first ore shipped from the Hillside claim returned over $350 per ton, the values being about equally divided between gold and silver. Soon after its discovery ore was found which returned nearly $1000 per ton by the carload, which attracted attention to the property, and numerous offers were made for it, all of which were refused. As development progressed it was found that the ore shoots continued, though the surface croppings gave no indications of it. It has since been extensively developed and thousands of feet of drift run on the various levels, and still these may be called superficial workings, as the vein is worked through crosscut tunnels. The average depth of the lowest level is less than 200 feet from the surface. The veins, of which there are several, occur in a silvery gray phillite and the ore shoots are 400 to 1200 feet in length. In 1890 the mine was sold to Dr. Warner of Buffalo, New York, who organized a company and attempted to float the mine for $3,000,000 giving certain guarantees of dividends to any who would subscribe to the stock. The scheme failed and the mine has since remained idle excepting during a short time when it was operated by the Warner Co., which was known as the Seven Stars M. Co. Dr. Warner defaulted on his deferred payments and by the terms of the agreement the property reverted to the former owners. It is this matter that is now the cause of pending litigation.

ARKANSAS.

MARION COUNTY.

The Standard Oil Co. and the Palmer Oil Co. are purchasing large bodies of land in this county which is believed to be underlain by lead and zinc ores. The Standard people have sent steam drills and have prospected many hundred acres. In nearly every case rich zinc ore has been found, in many places the rosin blende being so pure as not to require the use of a crusher. This zinc field extends over four or five counties. Marion county is the center.

CALIFORNIA.

Amador.

Jackson *Ledger*: At a depth of 160 feet the shaft in the Shenandoah, near Plymouth, cut an ore body 25 feet between the walls, in some of which free gold can be seen. The shaft is down over 200 feet.

Sutter Creek *Record*: S. R. Porter, Supt. of the Mutual mine, between Sutter Creek and Amador City, is sinking a new shaft on this property, which had been abandoned many years. The old shaft has also been cleaned out and retimbered as far as necessary. The latter 10 feet of sinking exposed two veins divided by a foot gouge seam, and an 18-foot crosscut reached a 4-foot parallel vein. The new shaft is 300 feet south of the old shaft.——At the Bay State mine, four miles north of Plymouth, drifting is in progress on the 700 level. Stockton parties have control of this property.——The Wheeler mine, near Plymouth, has been shut down.

Jackson *Republican*: Stewart & Savallo, who own a mine on the Pablo lead, Volcano mining district, shipped 5500 pounds of ore to Selby & Co. at San Francisco, Cal., and have received $640 from the run.——The Yellow Jacket mine, located three-fourths of a mile west of the Defender, Volcano mining district, is shipping ore to Selby & Co. at San Francisco, Cal.——The Defender mine near Pioneer is down 200 feet and the 4-stamp mill is crushing $60 rock which is taken from a 5-foot ledge.

Butte.

Marysville *Appeal*: At the De Long mine twenty men are employed in the mine and on the flume. The first flume put in did not carry sufficient water and a larger one is being built. The lumber for this flume is being cut by whipsaw, the Maxwell Bros. having a contract at $60 per M. feet.——The Butte Creek Power Co. at the Carter quartz mine on Butte creek has put an electric plant in and air compressors are in place. The shaft on the ledge is down 150 feet and the tunnels are in 300 feet. C. M. Spangler has charge of the machinery.——The Golden Trout Co. are employing twenty-five men on their 10-stamp mill, in the mine and in the sawmill. A. Hamilton has charge of the building of the quartz mill.

Oroville *Mercury*: Pres. W. P. Hammon of the Butte County Miners' Association has appointed a committee of five citizens to devise ways and means of entertaining the members of the American Institute of Mining Engineers when they visit Oroville. J. L. Gray, H. P. Stow, A. F. Jones, A. Ekman and N. Goldstein (ex-officio members, W. P. Hammon and O. W. Jasper, president and secretary, respectively, of the Miners' Association) are the members of the committee.

Calaveras.

A tunnel is to be run under the gravel deposit on French hill, a half mile north of Mokelumne Hill, for the purpose of reaching a basin of gravel presumed to be there. On the west side of the hill is a remnant of a gravel channel which was very rich when worked in early days. No work has been done there in many years and no one seems to know whether the deposit was worked out or not. The gravel is covered by volcanic mud and tufa.

At the Vorlander mine work has been suspended owing to the heavy flow of water in the shaft. C. M. Burleson, the Supt., states that a 5-inch pump will be required to handle the water.

The Thorp mine, near Fourth Crossing, is closed down.

S. H. Lucas reports that he is crushing thirty tons of ore daily in the 10-stamp mill at his mine, near Big Bar bridge, at a total cost of $1 per ton.

The Ford mine, near San Andreas, is to resume work after several weeks of idleness. The holdings of the Ford Bros. have been placed in the East and money provided for continuing development. The mine is 700 feet deep and has several levels. The veins are large but low grade. There is a 10-stamp mill on the property.

Wallace Gold Placer M. Co. has been organized at Stockton; W. Tucker, L. W. McKee, A. J. Taylor, H. N. Tremper and A. N. Petty; capital stock, $100,000.

The construction of the 120-stamp mill for the Melones Con. mine at Robinsons Ferry is being pushed with the utmost vigor. The ditch and tunnel connections will be in readiness for the beginning of work before the mill can be completed. The camp has grown into a good-sized village. In the early '50s it is said that more than 3000 people lived in tents and slab shanties on the steep slopes of Carson Hill, but the town now growing there will have more of permanence than the early village of Melones.

San Andreas *Citizen*: The new gallows-frame for the Fox mine, owned by J. V. Coleman of San Francisco, is completed and the shaft has been retimbered. Opening the levels will begin next week. It is the intention of Mr. Coleman to erect a 20-stamp mill on the mine.

Amador *Ledger*: The Sheep Ranch mine is being put in condition for the installation of a new plant under Supt. V. S. Garbarini. The collar of the shaft has been raised. The boiler room and engines have been set back from the shaft and their foundations raised. The new steam hoist is being changed to meet the conditions at the mine. The tunnel from the Ploche mine has been extended toward the shaft. The shaft has been retimbered to the depth of 300 feet. The shaft is 1200 feet deep, with extensive workings. Some of the levels are 1400 feet long.

San Andreas *Citizen*: The additional twenty stamps on the Lightner mine have been placed and are running on rich rock of this mine.——Arrangements are being made to resume operations at the Veritas property, near San Andreas.

Angels *Echo*: C. A. Lillie has bonded a gravel claim on Birney's ranch, one and one-half miles east of Angels, and is sinking a shaft to the channel. A whim will be put on and other improvements made. These channels are very wet and a pump will no doubt be needed before the channel is reached.

El Dorado.

(Special Correspondence).—The Gopher-Boulder and Dalmatia mines near Kelsey have been sold by J. C. Bell, through Col. D. H. Jackson, to J. C. Alvarado and associates for $100,000, part cash, the rest in twelve and eighteen months. The Dalmatia was the first mining property on this coast to be operated by electricity.

A contract has been let to the Simmons Co. for a 200 H. P. three-phase electric plant, the generating dynamo to be placed at Rock creek, where was located the old power house, which was burned down about two months since. This dynamo will supply power for the mines and mill. The present mill capacity is about 130 tons per twenty-four hours. There is a large quantity of low-grade ore in sight at present time which ought to yield a handsome profit to the new owners. Col. Jackson is in charge of the property for the new owners.

Placerville, Sept. 1st, '99.

On the 26th ult., at its regular annual meeting, at Placerville, the El Dorado Co. Miners' Association elected C. H. Dunton Pres., H. E. Pickett Vice-Pres., and C. H. Weatherwax Sec. The association will elect delegates in October to the annual State convention.

Placerville *Democrat*: On the Cinnamon Bear mine, in which A. D. Henderson, Supt. Deep Gravel M. Co., is interested, near the mouth of Big Canyon, just above Chili Bar bridge, a 5 foot ledge has been found.

Placerville *Democrat*: E. Bind reports recent developments in the Blue Gouge as encouraging. The surface improvements are being pushed rapidly. A mill is to be built before winter.

Mountain Democrat: It is reported that a shoot of $50 ore has been discovered at the Union mine.——At the 800 level in the Mt. Pleasant they have struck ore said to be richer than that which made the mine famous in its early history.——The machinery from the Gold Note is being taken down and hauled to the Alpine, near Georgetown, and the Three Stars in Placer county, both of which properties are being developed by E. W. Chapman.

Auburn *Republican*: I. L. Moore, Mgr. of the Lucky Marion mine, near Greenwood, reports that a decision has been rendered by Judge Prewett, in the El Dorado court, in favor of his mine and against Judge Williams and others who contested the title of the St. Louis Co. to the Lucky Marion. The mine cost the company $30,000 and has been in litigation two years, work having been suspended in the meantime. There is a 20-stamp mill on the property. The company will commence operations on the mine. An incline shaft is down 112 feet and the ore will average $7 to the ton.

Georgetown *Gazette*: The mill test from the Little Gem mine, near Josephine, made at the Esperanza last week, proved satisfactory. The work of retimbering the shaft will be commenced and a new hoist and pump will be installed and sinking resumed.

Fresno.

(Special Correspondence.)—The Ohio State M. Co., in the bed of the San Joaquin river near Millerton, near the mouth of Fine Gold creek, have at last strong hopes of success in their diversion of the stream, pumping dry the pool and getting the gold supposed to be in the bed. They have the pool nearly pumped out, and expect by Sept. 1st to begin getting gold.

Pollasky, Aug. 29th, '99.

An oil company has been formed at Fresno, capitalized at $100,000, in which Mrs. Phœbe Hearst is the principal stockholder. Her agent recently inspected the oil territory.

The Mammoth Oil Co. has been organized at Fresno; capital stock, $300,000; V. H. M. MacLymont, J. Berry, G. L. Hoxie, H. C. Smith, F. R. Lindsley.

Poso Oil Co., No. 1, has been organized at Fresno; capital stock, $100,000; W. H. Bradley, L. G. Hall, J. S. Bedford, G. L. Long, F. M. Hague, S. McKay, W. D. Foote.

Kern.

At the Little Butte mine, Randsburg, it is reported, all work has been suspended; the improvements are mortgaged for $2000.

At the Wedge claim some good ore has been taken out recently.

L. Bethune and C. Sears of Santa Barbara will work the claims of the Little Dick M. Co. at Randsburg. The shaft will be sunk to 100 feet and 100-foot drifts will be run and crosscuts driven.

The Kern & Trinity Mines Co. has been organized in San Francisco; capital stock, $200,000; C. L. Blair, E. C. Ward, W. H. Davenport, H. C. Cantelow, W. H. Waterhouse.

Mariposa.

The Green Mountain copper mine, eight miles northwest of Raymond, has been on fire during the past two weeks and is giving much trouble to the management. The ore is bornite, which, upon exposure to the atmosphere, oxidizes so rapidly that spontaneous combustion results. A quantity of ore broken down in the stopes took fire on Aug. 16th and clouds of sulphurous gas poured from the shaft. The workings were bulkheaded and were kept closed several days; but, when reopened, the fire was discovered to be still in progress and the bulkhead was replaced. Workmen who ventured into the mine were nearly asphyxiated by the gases.

Merced *Sun*: A. L. Briggs, who bought the Coppertown mines some months ago, is shipping high-grade copper ore, which contains $8 per ton in gold.——A thirty-ton water jacket will be built at the mines in Hunter's Valley.

Mono.

Bridgeport *Chronicle-Union*: Mr. Page, who is at the Arnot mine, has made a new find on the extension of the Arnot ledge on Green creek. A number of men located claims on the extension and vicinity. The ore shown was rich. The Arnot-Par Value mine is proving to be a valuable property, and the Green Creek district is attracting attention. The Arnot is rich in gold and galena. The ore will be concentrated and shipped.——It is reported that rich copper ore has been struck in the Copper Mountain mine at Jordan.

Nevada.

Nevada City *Herald*: The Rocky Bar placer mine on the South Yuba river, near the town of Washington, was sold to satisfy a judgment obtained by J. Kelleher of that district against J. D. Rockefeller, E. A. and J. O. Hays. Mr. Kelleher bid in the claim for $747.59.

Grass Valley *Tidings-Telegraph*: E. A. Roberts of Sacramento and W. H. Weldon of Grass Valley have men working on copper claims near Spenceville, the most important of which is the Last Chance.

Marysville *Appeal*: J. Sincock, who is prospecting a claim on the King ranch in the Buena Vista district, exhibits ore from the croppings which shows galena and iron. It is in serpentine and is identical with rock from the Brunswick. The ledge is from 1 foot to 18 inches wide.

Tidings-Telegraph: The Union Hill mine is to have a 16-inch pump with a capacity of 664 gallons a minute, running 8-foot stroke, eight strokes to the minute.

Placer.

Colfax *Sentinel*: The new 10-stamp mill of the Dutch Flat Blue Lead M. Co. is completed and operating, run by water power. It has a capacity of 75 to 100 tons of gravel daily. The company has begun an incline shaft to the surface 1000 feet from the mouth of the tunnel. The number of men will be increased to thirty. The gravel prospects well. S. L. Jordan is Supt.——W. Nicholls, Jr., of the Polar Star mine will resume hydraulicking as soon as the season permits.

Plumas.

Quincy *Bulletin*: B. N. Ivanisevich and five others are developing the Bluenose Con. gravel mine. The tunnel is in 650 feet and will run 150 feet. From the end of the tunnel an upraise of 150 feet will be made into the Bluenose channel. —— At the Plumas Eureka mine twenty men are working on tribute taking out pillars left by former operators. —— Fifty men are working at the Four Hills mine, where an electric plant will be put in. It will generate 180 H. P. and be run by water. The mine is reported to have a large body of gold-bearing quartz.

Riverside.

There is an area of broken hills fifteen to twenty miles south of Perris that have been but little prospected, though in a gold-bearing region.

There is an ancient river channel containing gold four to six miles southwest of Perris. It can be seen near the Good Hope mine and at several points between there and the San Jacinto river. It has been tilted with the uplift of the rocks of that section.

There are numerous small veins, rich in gold, west of Perris, some of which have been worked extensively, the quartz being hauled to arrastras in the neighborhood. In one locality are the basins of more than 100 arrastras, formerly used by Mexicans.

Los Angeles *Times*: Work has been resumed on the Leon mine, fourteen miles southeast of Perris.——The mica ledges recently discovered near San Jacinto are reported to be of commercial value.

Los Angeles *Herald*: The prospectors have found a mica ledge near San Jacinto, and parties are out in the mountains near and in other parts of the county looking for other deposits of mica. Two brothers named Trujillo and a man named Dunn in Chihuahua district, near Oak Grove, have found a ledge in which are sheets several inches square. The ledge is 8 feet thick.

San Benito.

The Dublin G. M. Co. has been organized at Hollister by F. W. Shields, Grass Valley; L. A. Spinelli, San Jose; L. W. Jefferson, J. M. Button and J. J. Croxon, Hollister; capital stock, $50,000.

San Bernardino.

San Bernardino *Sun*: The Tecopa M. & S. Co. has taken an abandoned mining property on the Nevada border and is preparing to begin work at the mine. The Tecopa mine was worked years ago and is ninety miles north of Vanderbilt, on the line between this county and Nevada. The Tecopa M. & M. Co. have headquarters in Los Angeles, with D. W. Shanks as president. The new company will equip the mine with machinery. It is stated that eight ore wagons will be in use hauling rock to the smelter.

San Diego.

A corporation known as the Great California M. Co. it is reported will take an option on the Dewey claim in Grapevine district, near Warner's ranch, if D. Clark does not take up his option.

L. N. Bailey has resumed work on the Kentuck S. crosscut tunnel near Banner. It is being driven through hard silicious mica schist to develop several gold-bearing veins which were rich near the surface. There is a three-compartment shaft on the property, 100 feet deep. The new tunnel will cut under it about 400 feet.

In the early history of the Cargo Muchacho district, a few miles south of Hedges, the most important mine and the largest producer was El Padre y Madre, located in a basin-like depression surrounded by the rugged, barren hills of the desert, at the western edge of the range. The formation is chloritic schist, traversed by numerous quartz veins, some of which were rich and the ore free milling for the most part. These veins were worked Mexican fashion by a series of pits and shallow shafts, the deepest 165 feet, yet the mine is credited with the production of a large amount of gold. The ore was crushed in the Cargo Muchacho mill, two miles distant, to which it was hauled and packed. Since it was shut down years ago nothing has ever been done with the property, though it is doubtful that it is exhausted.

Yuma *Sentinel*: The Colorado mine, owned by A. Modesti and F. Avila, employs twenty-five men. Six thousand dollars worth of ore was shipped during August.

Santa Clara.

The Harmony Iron Co. has been formed, to explore for and mine iron ore, by M. H. Chenoweth, E. A. Hayes, J. O. Hayes, M. B. Hayes, C. L. Hayes, W. P. Lyon, Jr., and E. C. Lyon, Eden Vale; capital stock, $1,000,000.

Shasta.

The Afterthought group, recently bought by A. H. Tarbet and associates, consists of six claims on the same zone as the Bully Hill property, bought by J. R. DeLamar recently for $250,000. It was worked originally for silver; the ores were quarried from the vein, that is 50 feet between walls. In this quarry, 40 feet deep, large bodies of ore have been exposed. At each end of the quarry copper sul-

phides have been exposed, while a solid body of ore 26 feet in width is uncovered. There are several tunnels that cut the vein at greater depth that show the copper sulphides. Mr. Tarbet says that they will follow up the purchase of the property with erection of a smelting plant.

Redding *Searchlight*: The Gold King quartz mine, one mile north of the Rabbit claim on Muletown mountain, was sold last Monday by J. G. McDaniel of Redding to J. V. Cooke of Colusa. The Gold King has been worked for three years. Development includes a shaft, tunnel and several cuts. A lot of sorted ore sent to Selby's assayed $700 per ton. Mr. Cooke will let the contract for a tunnel to crosscut the three veins.

Redding *Free Press*: L. F. Sheppard, Supt. of the Old Spanish mine in the Lower Springs district has started another shaft on the vein.——Myer & McGinnis, owners of the Scorpion mine in the Whisky Creek mining district have taken out ore recently which carried 37% copper. The ore also carries gold and silver.

Sierra.

F. M. Manson has sold the Gray Eagle mine in Kanaka ravine, near Gold Point, to Messrs. Hastings & Wilbur. They have bought a 10-stamp quartz mill from one of the mines near Nevada City and will transport it to the Gray Eagle mine.

Grass Valley *Union*: Fifty sacks of sulphurets from the Triple Pocket mine have been sent to the Selby Smelting Co.'s works at Vallejo Junction.

Downieville *Messenger*: F. M. Manson reports that he has sold the Gray Eagle mine in Kanaka ravine, near Gold Point, to Hastings and Wilbur. Last week they bought a 10-stamp quartz mill from one of the mines near Nevada City and will have it transported to he Gray Eagle mine.

Siskiyou.

Yreka *Journal*: G. W. Grayson of Oakland, Cal., has made a deal with Bennett, Smith & Co. for their mine at Know Nothing creek.

Yreka *Journal*: At the Schroeder mine on Deadwood in a short time the mill will be started up.——The Wheeler Co., sinking to bedrock at Greenhorn, south of the Blue Gravel mine, has not reached bedrock, the work progressing slowly owing to the large quantity of water.——Mr. Scott, the former Supt. of the Mount Shasta mine, is developing a mine near Hornbrook.

Yreka *News*: At the Barron mine, on Knownothing creek, an arrastra is crushing one ton of ore daily.——The location on the south extension of the Gold Run mine has a 4-foot vein of high-grade ore.——On Knownothing creek, it is reported J. Hogan has a vein 5 to 8 feet wide. Free gold is visible in it. He panned out $50 in one day from a rich portion of the vein.——Forrest & Campbell are extracting $7 per man daily from their claim on Knownothing creek.——Ore of the value of $60 per ton has been found in a 16-inch vein on the Wolverine ground on Knownothing creek by A. Heglan.——The summit of the Salmon river range was covered with a light fall of snow last week. —— Brown & Reeder have bonded their mines to W. H. Crocker who will erect a mill.——The Summerville M. Co. has completed a trestle to convey water across Indian creek to their mine.——The Golden Eagle mine on Indian creek is building a 6-stamp mill. —— At the Wheeler blue gravel mine sinking has recommenced. The shaft is down 130 feet and bedrock nearly reached. Tests of the gravel show gold.——One hundred and ten sacks of high-grade copper ore have been shipped from the Crawford & McGowan mine on upper Smith river, San Francisco.

Trinity.

The Enterprise mine at East Fork will increase its milling plant by the addition of five stamps, recent development having exposed a large amount of ore.

Santa Rosa *Republican*: Dr. M. M. Shearer of Santa Rosa has for months kept a prospector in Trinity county on a grub stake. The prospector has found and located copper-bearing lands. Samples of ore are reported to be rich.

Tuolumne.

The town of Carters, which for a time will be the terminus of the Sierra railroad, is growing rapidly.

The Dead Horse mine at Carters is closed owing to a scarcity of water.

The project to run a long tunnel from the Stanislaus canyon under the limestone potholes of Columbia Flat has been abandoned.

A 20-stamp mill is to be placed on the Mount Jefferson mine at Groveland. J. Meighan is Supt.

A 5-foot ledge at the depth of 335 feet is reported in the Longfellow at Big Oak Flat.

At the Accident mine at Big Oak Flat, the shaft is down 300 feet with good rock from surface to bottom. J. Meighan has charge and intends to put up a 20-stamp mill.

The Sonora Quartz Mine Development Co. was incorporated at Sonora by F. L. Coombs, F. B. Lloyd, R. G. Hart, Sr., H. R. Wiley, H. E. Wise, J. Kirby, J. Gartland, F. Homer, A. N. Hart; capital stock, $500,000.

Sonora *Independent*: Near Parrot's Ferry on the Stanislaus river, at the Deozzle mine, operated by an Illinois company, fifteen men are at work.——A company will commence work at Prether Bar, Parrot's Ferry, where it is expected a deposit of gold will be found. A 35-H. P. engine will operate an air compressor and centrifugal pump.

Union-Democrat: The development of the Crœsus mine, owned by T. G. Winwood and W. Carter of Summersville, has been commenced by San Francisco capitalists. A shaft is being sunk to the vein.——At the Kincaid Flat gravel mine sinking is progressing.——Saturday two miners working in a drift of the Excelsior mine near Confidence were nearly drowned by a sudden inflow of water which broke in from the old workings.

COLORADO.

CHAFFEE COUNTY.

Leadville *Miner*: At Granite a new hoisting plant is being erected on the Magenta and a mill is in contemplation for the Cuba mine in Low Pass canyon. The mine was recently bought from Captain McCannon by a Cripple Creek company who have put on a hoist and are sinking a shaft. They have 2½ feet of quartz, making a rich concentrate. A shaft is also being sunk on the vein of the Spondulix, down 35 feet and showing a pay streak of gold-bearing hematite.——In the Saguache range veins of zinc and copper ores are reported, which have never been prospected.

CLEAR CREEK COUNTY.

At the Mendota mine, at Silver Plume, F. A. Maxwell is building a concentrating mill to treat the Mendota dump. Two 20 H. P. electric motors will be used to run the mill.

The Griffith is contemplating the addition of machine drills and possibly a concentrating mill at that mine.

W. Rogers is getting the machinery of the Debbins mill in order to concentrate the Paymaster dump in the East Argentine district.

The Humphrey Zinc Spelter Co. have completed their 150-ton concentrating mill near Montezuma. They have 5 feet of zinc-bearing quartz.

Wolfe, Robeson & Seifried, owners of the Stevens mine, have men cleaning out the levels of that mine, and fifteen lessees are taking out ore.

McLaughlin & Co., leasing on the Mathews tunnel, are shipping good ore every week.

Denver *Republican*: In widening the sump at the Sun & Moon mine a new ore body has been encountered on the east side of the shaft.——Jones & Jones, working the Brazil, near Freeland, have a body of sulphuret ore which is carrying native silver.——A local pool recently took charge of the Silver Link mine and began cleaning out one of the levels. To put in new timbers it became necessary to blast into one of the walls. One of these shots opened an ore body which had never been disclosed before. In the lower level of the mine a body of lead ore is opened.——The Frostburg mine at Silver Plume is showing up a good grade of mineral. Two classes are shipped, the first running 28 ounces silver and 65% lead and the second running 110 ounces silver and 24% lead to the ton.

EL PASO COUNTY.

Woodland Park *Times*: The tests by the Halt process on the Sandstone ores of Woodland Park district have been made. They were conducted by Dr. I. P. George under lock and key, with the solution and instructions furnished by C. Halt. The tests were made at the temporary mill at the Manitou Park hotel on ore that Mr. Halt had given $5 in gold on before. The doctor's tests resulted in returns of a trace to 1.5 cents per ton. Mr. Halt explained the circumstance by saying he had inadvertently omitted a certain ingredient of the process.

GILPIN COUNTY.

J. W. Cairns, formerly of Boulder, has associated himself with Eastern parties who have taken a lease and bond on the Hayes & Wheeler property on Quartz hill. A new shaft house is being erected and a plant of machinery is in place. This building has been put up over the west shaft, which is 110 feet deep.

A new shaft house is being built on the Freedom lode on Winnebago hill by the Freedom M. Co., under the management of S. Hoskin. The plant, consisting of a 45 H. P. hoist and a 60 H. P. boiler, is in place. The collar of the shaft has been raised 6 feet. The shaft on the Freedom has been sunk 400 feet and will be sunk to 1000 feet. This lode is supposed to be the same as the Rialto vein.

Nevadaville people are working as a pool on the French mine on Quartz hill. Shipments of smelting ore have given values of $65 per ton. They have started a new shaft 400 feet westward, which will be sunk 200 feet to make connections with the old working shaft. The property is owned by Willard Teller and Judge Wells of Denver.

Prof. E. C. Linderman has started the Wide Awake stamp mill and is running twenty stamps on ore from the Stewart mine and other claims in that vicinity.

The water in the California mine is down to 1745 feet from the surface, where it is being held while cleaning out the 700 level. A new flat steel cable over 2000 feet in length will be put on the hoist. A small force of lessees are working in the fourteenth and fifteenth levels, and taking out mill and smelting ore, the latter carrying over $100 per ton. This shaft is the deepest of any gold mine in the State, being 2230 feet deep.

Regular shipments of milling ore are now being made from the Gladstone property of the Gilpin & Boston M. Co.

The Kansas Burroughs Con. M. Co. has purchased the English-Kansas mine on Quartz hill, embracing 700 feet on the Kansas vein, east of and adjoining the Pease - Kansas property.

Denver *Republican*: H. P. Barbour has started up the mill in Moon gulch, recently leased to handle the ores being mined on Jenny creek. The plant has a capacity of thirty tons a day. The underground force has been doubled. A good body of mill ores carrying pockets of chlorides has been opened in a shaft started last month. At 40 feet this working is entirely in ore.

GUNNISON COUNTY.

The Black Queen mine, near Crystal, is reported sold for $150,000 to Warner Miller of New York. The property consists of four claims—the Black Queen, Fargo, Legacy and Last Chance. The Fargo made a copper strike during the past month from which a car of ore has been shipped.

HINSDALE COUNTY.

The managers of the Ute & Ulay, Hidden Treasure, Lellie and Golden Fleece have adopted the eight-hour plan, with no reduction in wages, notwithstanding that men are scarce and forces of all the mines are short of the number they need.

The ore shipments from Lake City have run from three to five cars per day all summer, the shipments being principally to the Philadelphia smelter at Pueblo.

The new mill being erected by the Golden Fleece people is nearing completion and will treat the low-grade ores in the mine and on the dumps which have been accumulating for many years.

Above this mill the Contention people are driving a crosscut tunnel, which has reached the vein and is piling up a quantity of milling ore.

The Monitor mine, owned by local parties, is taking out bismuth ore. A car of this ore was shipped recently.

LAKE COUNTY.

Leadville *Miner*: Machinery is on the way for the Elgin smelter. It will have a capacity of 300 tons daily.

SAN JUAN COUNTY.

The company that has leased the Zuni mine is incorporated under the laws of Colorado and is known as the Commonwealth Leasing, Mining & Prospecting Co. R. W. Heflin is Supt. It is the intention to start another tunnel to tap the vein at greater depth, and a tramway and mill are contemplated.

The Syndicate G. M. Co. recently shipped a ton of ore valued at $10,000. This company employs twenty men. A building large enough to accomodate sixty men is being constructed.

Hass, Cooper & Harwood have claimed a vein of tungsten ore on Cement creek.

Silverton *Miner*: The sale of the Excelsior group of five claims on Boulder mountain was made last week by the first payment of $3000. The owners were J. and C. N. Carver and J. Butler, and the purchase price is $30,000. There are fifty tons of ore on the dump. The Excelsior has a vein of lead ore 6 feet in width and another vein 4 to 6 feet of free milling ore.——Another strike was made in the Ridgway in Maggie gulch last week in the new 400-foot crosscut at a depth of 200 feet, where 2 feet of ore was found that will run 25 ounces gold and 1000 ounces silver. The force of miners has been increased.

SUMMIT COUNTY.

Breckenridge *Journal*: Recently M. G. Frey and W. Lawver leased and bonded to J. M. Larsen, of Aspen, the Hancock and O. K. lodes, on the north slope of Glacier mountain. In the past these claims produced a good grade of silver and lead ore. The mines contain large bodies of low grade concentrating ore. Mr. Larson is considering the building of a mill of sufficient capacity to treat the ore and to do custom work. The mill will be similar to that of the Smuggler at Aspen.

Breckenridge *Journal*: The Pennsylvania mine at Rathbone is one of the largest producing mines in Summit county. The past four years the Pennsylvania has been under the management of F. Graham, and since that time has produced 150 tons of shipping ore per month. Within the past year a new mill, designed by Mr. Graham, has been built and is in operation. It is located 1000 feet below the mine and the ore is transported by a gravity tramway. Its capacity is fifty tons every twenty-four hours. Four large dumps will be run through the mill, besides which Mr. Graham estimates that there is sufficient ore broken in the mine to keep the mill running for three years. The Pennsylvania is working twenty-five men in the mine and mill.

TELLER COUNTY.

Victor is being rebuilt and real estate is worth more than before the fire.

The Independence mine is reported to have made $540,000 since the incorporation of the new company.

Cripple Creek *Times*: The Creston Leasing Co., working the Jack Pot mine, has declared a dividend of $80,583.80, the profit on ore mined in July. The money the Iowa men expended before getting pay ore represents a few hundred dollars per share, and now it is returning a hundred fold.——The Independence mine has developed in the stope from the third level an ore body 60 feet wide in places. In the crosscut from the fourth level a new vein 3 to 4 feet wide has been opened since the mine changed hands, that is settled for in carload lots at six ounces. This shoot is 140 feet long. The Independence is averaging 3000 tons a month of four-ounce ore, and 75% to 80% represents net profit.——P. E. Johnson has taken a fifteen months' lease on 350 feet of the Gray Eagle, Mountain Peak and Stella A. claims, at Grassy. The contract provides for 20 feet sinking per month, and 25% royalty.——The Pinnacle is taking free gold from the 100-foot level, an average of two cars a day being sent to the mills and smelters.——The Mountain Beauty will again commence to break ore in the 100-foot level, and regular shipments will be made.——Lessee Lambert, on the Lost Lillie, on Copper mountain, is hoisting ore from the 150-foot level. The vein is 5 feet wide and assays $30 to $60. This was found by putting a shot into what was supposed to be the foot wall.——A rich streak of ore has been opened in the upraise from the 300-foot level of the Maloney workings of the Orphan Belle claim. The company will continue the upraise to the surface.

Denver *Post*: Production from the lease operated by Magner and others on the Minnie Belle fraction of the Wilson Creek Con. M. & M. Co. will reach little more than 200 tons during August. This small showing is due to the fact that until the reopening of the smelters the lessees had no market for their ore. —— Beginning Sept. 1st sinking will be resumed, and the shaft will be deepened from 380 to 430 feet. The level to be started at the depth will be the sixth in the Magner workings.

Victor *Record*: The Sellers, Stephens & Co. lease on block 2 of the Mountain Beauty is in bonanza. The ore in the 100 level will average fifty ounces across the vein, while the mud seam, 6 inches wide, that lies alongside, is impregnated with coarse gold. The lessees have 309 feet of ground. At a depth of 240 feet they are crosscutting.——In the third level of the Whipp & Glenn lease on the Pinnacle, near the shaft, 3½ feet of ore that assays from $30 to $100 has been cut. After passing through a barren zone in the second level the workings have cut 6 feet of ore of good grade.

IDAHO.

(Special Correspondence).—Cottonwood is fifty miles southeast of Lewiston and eighteen miles from Grangeville. From Cottonwood to Salmon river is fifty miles, and here are located a number of gold prospects. Salmon river is half a mile from the claims and parallel with them. The formation is porphyry, running north and south, veins of gold-bearing quartz crossing the formation east and west. The quartz, iron-stained, prospects well and is impregnated with auriferous pyrite.

Col. Danforth of Lewiston, who has several claims on the belt, has run in on a vein, 3 feet wide, which at the end of a 50-foot tunnel has widened to 4¼ feet and averages $30 per ton. On the east and west side of the porphyry is marble or limestone; above, or east of the limestone 1500 feet, is a body of timber. In addition to the river, there are on the south end two large creeks. Work can be prosecuted the year round. Assays on some of the quartz ran as follows: $619.48 gold and $14.46 silver; a cube of iron, $25.63 gold and $1.20 silver; a leached piece with light-colored iron cubes, $4.13 and $4.75 gold.

Most of the outcrop is free, but there are some sulphurets, and, where work has been done, sulphurets predominate.

A sale of the Black Jack for $10,000 failed, owing to a disagreement.

The veins vary from 2 to 6 feet in width.

Cottonwood, Aug. 20th, '99.

BLAINE COUNTY.

Hailey *Times*: J. Flemming has bonded his Little Johnnie, Lame Deer and Collier Boy claims and water right, on the Hailey Gold Belt, to L. S. McLure of San Diego, Cal. All are promising claims, situated easterly from Camp creek. There is a 250-foot tunnel on the Little Johnnie, a 40-foot shaft on the Lame Deer and cuts and prospect holes on the Collier Boy. It is stated that the price to be paid is $20,000.

ELMORE COUNTY.

F. R. Reed has a placer property which is being prospected with the view of determining if it will justify a plant. The work of prospecting is being done by the Pennsylvania Placer Co., in which Mr. Black and J. Leisenring are stockholders. T. F. Van Wagenen is in charge of operations. This property embraces 4000 acres located on the south fork of the Boise river, five miles below Pine. The gravel has a depth, where exposed, of 200 feet, but it is not known how far it extends. Part of the property is a meadow of 800 acres, which may be valuable as placer ground. The entire tract is being surveyed and prospected. In connection with the ground the company controls 20,000 inches of water. To put this on the gravel and fit up for working will cost $200,000. With the placer are five quartz claims.

IDAHO COUNTY.

Cuprum *Standard*: W. H. Hancock, Supt. Boston & Seven Devils Copper Co., will commence development work on the South Peacock and Decorah mines, employing thirty-five or forty men.

NEZ PERCES COUNTY.

Owners of the Imnaha copper properties, near Lewiston, have received returns from Butte, which show a value of $28.50 in copper to the ton, based on a valuation of 19 cents a pound. The ore was the first from the district and was taken from the surface of the ledges. Assays of ore recently brought out show 13% copper.

OWYHEE COUNTY.

Spokane *Chronicle*: A mill, probably a cyanide plant, will be bought for the properties of the Hoosier M. Co. near Silver City. The mines adjoin the DeLamar properties and are said to have bodies of low-grade ore. F. W. Wegner is the Mgr. of the company.

SHOSHONE COUNTY.

A Boston syndicate has bought a large number of placer mining claims in the Cœur d'Alene district, along Prichard and Eagle creeks. A large dredging and hydraulic plant will be put in and the whole district, about twenty-three miles in length, worked.

Union miners are adopting the permit system inaugurated by the State authorities shortly after martial law was declared in the Cœur d'Alene district. Dozens of union men are applying daily for permits but in numerous instances they are denied.

MINNESOTA.

ST. LOUIS COUNTY.

Up to Aug. 1st the iron mines of the Lake Superior region produced and shipped since the first of the year 5,781,000 tons of 2240 pounds. In the Mesabi range the Mountain Lion mine began the season by shipping 5000 to 7000 tons of iron ore a day, but recently the shipments have run from 8000 to 11,000 tons a day.

The Fayal mine will ship a total of 1,000,000 tons this season.

MISSOURI.

JASPER COUNTY.

In the zinc fields the country is gently undulating. The mineral is in a blanket formation, in flint or chert upon lime, under the clay and soil from 10 to 200 feet from the surface. Most of the shafts are getting ore from less than 100 feet depth. The ore is in flat shoots and one shoot may lie below the other. When one is worked out, another is opened up.

Prospecting is done by churn drills and shoot holes are bored at a cost of $1.25 per foot. When mineral is found a shaft is sunk. The sinking of shafts costs $4 per foot. Not much drifting is done away from the shafts. It is cheaper to sink a new one than to follow up a shoot for a distance. The ore is hoisted and jigged by hand or steam jigs, and each mine has its own mill for crushing and jigging. The ore is washed clean. The clean blende will run as high as 63% zinc. It is sent from the mines to the local smelters and also shipped elsewhere. The mines furnish most of their own water for washing and carrying the ore through the mill.

MONTANA.

JEFFERSON COUNTY.

Whitehall *Zephyr*: E. R. Holden & Co. of New York have secured control of the Hope mine at Basin and will build a concentrator and start up the mine. The mine has yielded $700,000. The Basin Gold & Copper Co. is the name of the new company. The main shaft on the Hope is down 900 feet.

SILVER BOW COUNTY.

The Parrot smelter closed down Aug. 24th and the matte on hand will be sent to the Anaconda for treatment. It is understood that the smelter will be permanently closed and ores from the Parrot mine sent to smelters at Anaconda hereafter. The Parrot smelter has not been running full blast for some time.

It is locally stated that experts in the employ of the Rockefeller interests in the Amalgamated Copper Co. are making an inspection of the mines in Butte and smelters in Anaconda.

NEVADA.

HUMBOLDT COUNTY.

The Glasgow & Western M. Co. intend to enlarge their plant at Golconda to 400 tons daily capacity. O. Stahlmann, Gen. Mgr. of the company, is now engaged upon the details of the plans.

The Utica-Bullion M. Co., organized by H. Greeley, to develop mining locations near the outlet of Humboldt lake in the early sixties is still in existence. The company expended $30,000 in the building of a 10-stamp mill.

STOREY COUNTY.

The following is the latest telegram regarding the pumping operations on the Comstock:

VIRGINIA, NEV., Aug. 31, 1899.

To Aug. Waterman, Secretary Comstock Pumping Association, San Francisco: — At 6:30 this morning the water was down 39 feet 9 inches below the 1950-foot level. No. 1 elevator has been running continuously. The two elevators were run together for about an hour. September 1 Joseph R. Ryan will assume the duties of superintendent of the Comstock Pumping Association.

The Comstock mining companies have been signing the contracts with the electric power company the past few days. The companies first signing are the Con. Cal. & Va., Ophir, Mexican, Sierra Nevada and Union Con. The Utah Con., Best & Belcher, Gould & Curry, Savage, Chollar, Potosi, Bullion, Alpha Con., and all the Gold Hill and other Comstock mining companies it is expected will do likewise.

OREGON.

BAKER COUNTY.

(Special Correspondence).—The property of J. Arthur, consisting of 300 acres of placer ground and twelve quartz claims, is under bond for $200,000 to Eastern capitalists. This property was taken up, with the water right, eighteen months ago, at the cost of location.

Cornucopia, Aug. 28th, '99.

Spokesman-Review: Another rich pocket has been found in the Golconda mine in the drift on the 250 level and several sacks taken out. It is estimated that $60,000 worth was sacked in an hour's time; this, with the strike made some days ago, making over $100,000 taken from this drift in the last few days.——The stamp mill is ready to begin operations on the Great Northern mine at Canyon City. The property is owned by Mr. Harris and associates of Salt Lake City. The vein is free-milling and 35 feet wide.——The Miner claim, in Cable cove, is reported sold to Pendleton parties. This claim is on the Imperial lead, below that property, and has several hundred tons of ore on the dump. It has been idle for some time.

CROOK COUNTY.

The Silver King mine, which recently sold for a large amount, is thirty miles north of Prineville. The purchasers are P. J. Quealy of Rock Springs, Wyo., and J. F. Edwards of Salt Lake, Utah.

JACKSON COUNTY.

During the past year 110 placer and 224 quartz mining locations were recorded in Jacksonville.

JOSEPHINE COUNTY.

Gold nuggets valued at about $12,000 are exhibited the Medford Bank, a part of the cleanup of the Sterling M. Co.

SOUTH DAKOTA.

The smelter plant of the Golden Reward Co. was burned at Deadwood Aug. 28. The plant was the largest of its kind in the Black Hills.

UTAH.

BEAVER COUNTY.

The Horn Silver mine, at one time a large producer of lead-silver ore, is now shipping high-grade copper ore to Salt Lake smelters.

GRAND COUNTY.

The International Copper M. Co. has been incorporated by S. A. King, W. H. King, J. W. Burton and H. A. Hatch. The company owns nine claims in Beaver basin, thirty-eight miles southeast of Cisco, on the line of the Rio Grande Western Railway, twenty miles east of Moab, in the La Sal country.

IRON COUNTY.

The Johnny mine at Stateline is shipping to Salt Lake ore that will yield $100 per ton in silver and gold, and it is said that 4 feet are exposed, occurring in which is a 10-inch paystreak which shows free gold and is rich in silver.

JUAB COUNTY.

The pyritic ores in the mines of Treasure hill, at Diamond, between that camp and Silver City, is interesting those conversant with pyritic smelting. An analysis of the ores recently encountered in the Tesora and those on the dumps in the Shoebridge Bonanza show that these ores possess the elements essential to pyritic smelting, and charges at local smelters would be greatly benefited by such a plant. Col. O. P. Posey, who has operated pyritic plants in other localities says the ores are adapted to the scheme, and that with such a plant the producer should realize a great saving on the cost of treatment. The erection of a plant is under consideration.

At the La Reine in Tintic ore is exposed in every opening on the vein. In an upraise are 15 feet of ore, with no wall in sight. An average from this body gave 8% copper and 114 ounces silver.

Shareholders of the Centennial Eureka have authorized the board of directors to sell at any time within six months after August 1st last the entire property of the company for $2,100,000.

Tintic *Miner*: At the Centennial Eureka changes will be made in the method of transporting ore to the railroad by means of a tramway to the tracks. The force will be increased. There is enough shipping ore in sight to pay the purchase price of the mine, besides several thousand tons of milling grade.

Tintic *Miner*: On the 300 level the Showers Consolidated has found rich silver-lead ore 2 feet wide which assays 50% lead and fifty ounces in silver. In connection with this deposit is another vein carrying a small percentage of copper, 15% lead and $2 in gold. The vein is wide between the 200 and 300 levels and is thought to be the junction of the Bowers and Showers veins.

SALT LAKE COUNTY.

Bingham is in West Mountain mining district, twenty-five miles southwest of Salt Lake City, in the Oquirrh range. The first discovery was made in the early '50s, when lumber men found galena rich in silver. It is said the lead ore was smelted into crude bullion containing as high as 1000 ounces silver per ton and melted into bullets. About 1870 the placers were worked to large profit and in 1871 the ores of the Old Jordan and Galena, Old Telegraph, Winnamuck, Trewaukee and other mines were being worked in smelters. Early in the seventies the Telegraph group was sold to a French company for $3,000,000. The new company worked it with profit. On this zone are the Highland Boy, Giant, Niagara, Old Jordan and Galena, Utah and other noted mines. The Brooklyn workings are the deepest in Bingham, being 1500 feet below the surface, but, generally speaking, the great volume of ore thus far taken from these mines is from the upper portions of the workings. It has now developed into a sulphide proposition of great extent and concentration must become an important factor in their further development. In former years the bulk of the ore taken from the district were silver-lead ores, running from 30% to 60% lead, 8 to 60 ounces silver and $4 to $100 gold per ton. The operation of these mines paid, but the copper ores were neglected, being too low grade at that time to attract attention. It is to the recovery of the copper as well as the other valuable metals in these ores that particular attention is now being directed, and large capital has been interested to this end. The consolidation of these various mines into large groups is an important feature in the economy of future operations in the district.

The Dalton & Lark has a body of ore exposed that shows 11% copper and six ounces silver per ton in the north drift off the 850-foot level, where the vein is 5 feet wide. The management is considering the hydraulic ejector system of draining the property.

Bingham *Bulletin*: The Last Chance mill, which has been shut down for a year, is to start up. Several thousand tons of ore, containing gold, silver and lead, is ready for the mill. The plant will handle 100 tons of ore daily. The mine has produced several million dollars.

TOOELE COUNTY.

Mercur *Mercury*: It has been decided to increase the capacity of the mill at Manning to 600 tons daily capacity. It will be still further increased next year to 1000 tons daily. The building of roasters has been postponed, as experiments have not yet determined which is best suited to the ore.—The contractors on the upraise shaft from the tunnel level on the Rover broke through at the surface last Wednesday at 160 feet. A hoisting plant will be put in at the shaft.

WASHINGTON.

OKANOGAN COUNTY.

The Palmer Mountain tunnel has been driven 2175 feet. Fifteen locations have been added to the twenty-seven and taking in thirty parallel veins 2 to 16 feet wide on the surface. Twelve veins have been crossed, ranging in width from 5 to 42½ feet and carrying ore veins of solid mineral of 2 to 35 feet.

On Mount Chapacca the Golden Zone, a company composed of Pittsburg men, is working fifty men and having 2000 feet of work done on the property. The ore assays $30 in gold.

On Little Mount Chapacca the Six Eagles will work twenty-five men.

STEVENS COUNTY.

The Crystal Butte mine, 1½ miles south of Chesam, has put in a 10-stamp mill and concentrator with a capacity of twenty tons per day. The company has 100 men on the payroll. The vein is from 6 to 29 inches wide, but is continuous and rich. There are 1000 feet of tunnels and shafts. The War Eagle, four miles west, is putting on forty men. They are 80 feet down and have run a crosscut in ore resembling that of Republic.

At Summit camp, twelve miles west of Republic, limestone that assays 98% calcium carbonate has been found. Gold ore has been discovered in the same vicinity in a large ledge. The surface shows 40 to 60 feet wide. Assays made show values of $5 per ton. The property is owned by the Republic Gold Mining & Lime Works Co.

W. S. Willis reports the finding of rich silver-lead ore in the property of the Apex M. Co., a Spokane corporation, which is on south half of the reservation.

Spokesman-Review: The Princess Maud winze at Republic is reported improving. The winze is sinking on a shoot, the apex of which did not reach the surface.

WYOMING.

CARBON COUNTY.

The Union Pacific Railroad will build a branch line to the new copper mines at Grand Encampment.

The Hagerty mine is reported to run 60% per cent copper and $30 gold to the ton.

The Charter Oak ore runs 35% copper and $30 gold per ton.

The Meter mine carries galena with $15 silver per ton.

FOREIGN.

AUSTRALIA.

The gold yield of Queensland for the six months ended June 30 was 451,400 ounces, as compared with 427,600 ounces in the corresponding period of '98.

The surface ores of the Broken Hill Proprietary Co. in New South Wales are excavated in a cut 200 feet deep. An extension has been made to the concentration plant, and a special plant for the treatment of slimes has been added. Experiments in making a clean zinc sulphide concentrate from mixed ores are reported as resulting satisfactorily, and several lots of zinc sulphides have been shipped.

London *Mining Journal*: The block of telluride sent to the Adelaide School of Mines by Mr. Warden Gee (South Australia Mines Department) for assay gave twenty-one ounces gold to the ton. The excitement on the South Australian and Victorian stock exchanges is at fever heat. Five companies were floated within a few hours. The Wortupa Reward Development Syndicate shares, in which shares were £100 each, have gone to double that amount in a day. The other companies' shares went to a premium of 50% at once. This discovery will lead to a thorough opening up of the lower northeastern area, especially as the telluride is associated with chalcopyrite and is in the heart of the great copper belt.

BRITISH COLUMBIA.

The new town of Phœnix, 4½ miles from Greenwood, is growing rapidly. There are five or six large producers in and around the town. It is proposed to build a tram line from Greenwood to Phœnix.

The main line of the Canadian Pacific Railroad will be completed to within four miles of Phœnix by Sept. 10, and spurs are being built to the prominent mines.

The eight-hour law has resulted in closing a number of mines in Greenwood district. The scale of wages now paid is: Hammersmen and muckers, $3 for eight hours; power drill men, $3 50 for eight hours; all men in wet ground 50 cents per day extra.

Favorable development is reported on the Elise at Ymir, owned by the Lerwick G. M. Co. From the bottom of the shaft, 115 feet deep, a drift has been run 162 feet. There is a streak 8 inches wide which gives assays of $40.42—$18 being silver, the balance gold. Besides the paystreak there is a width of 4 feet of quartz assaying $9.11. The directors of the company intend to buy a steam hoist and pump and to carry on the work of development on a larger scale.

There is no trouble between the mine owners and miners in East Kootenay. The Fort Steele *Prospector* says the owners are paying $3.50 per day for eight hours work, and it is difficult to get men in sufficient numbers.

While grading on the Canadian Pacific extension workmen have uncovered ledges of ore carrying copper, gold and silver. The richest ledge was found near Cascade, on the Columbia & Western Railroad, building from Rossland into the Boundary creek district. Assays from the surface give $40 to $50 per ton. McKenzie & Mann have filed on the property and will develop it. Two smaller ledges have been uncovered by the grading crews.

Spokane *Chronicle*: The crosscut tunnel being driven on the Rambler-Cariboo mine, in the Slocan, to tap the ore body, has reached the ledge. The Rambler has not been shut down by the eight-hour troubles and will soon begin shipping ore. The average value of the ore heretofore shipped has been 130 ounces of silver and 25% lead to the ton.

MEXICO.

(Special Correspondence.)—During the rainy season in Mexico, which commences about June 20th and continues into September, little prospecting is done. At Fuerte, Sinaloa, Mr. Snyder is working his Santiago mine. He has three ore shoots and is drifting east from the shaft at the third level, in which direction the ore carries more gold. He is going to build a mill in October.

Fuerte, Aug. 10th, '99.

J. B. Frisbie is reported to have sold his interest in the American mine, adjoining the Esmeralda, in the El Oro district, to an English syndicate for $1,200,000.

Modern Mexico: An 80-stamp mill is to be built at the Esperanza mines, El Oro district.——The Cuchilla gold mine near Altar, Sonora, has been bought by California parties for $30,000. Another deal at the same place was the sale of a gold mine by J. J. Pompa for $17,000. The Calera, also gold, near Magdalena, is bonded for $60,000, and a New York syndicate is reported to have bought the Copita copper mine for $3,000,000.——At Sonora the El Cobre Grande mine, in which J. Shirley and others are interested, is to be developed. J. H. Costello of Buffalo has bought a control in this mine and put C. O'Keefe in charge as Asst. Gen. Mgr. G. Mitchell will be metallurgist.

James Shirley has sued to enjoin George Mitchell, former president of the Cobre Grande mines in the Cananea district, Mexico, from disposing of his stock to J. H. Costello, who recently took a lease on the Cobre Grande.

NEW GUINEA.

South African Mining Journal: Miners have done fairly well exploring gullies in the mountains near the Dutch boundary of New Guinea. The difficulties presented by the existence of almost impenetrable bush and the almost entire absence of roads to the interior, as well as the hostility of the natives and the deadly character of the climate, almost preclude exploration on a large scale. Those miners who have lived to return to Australia state that the gullies where they had been working had been practically exhausted.

NEW ZEALAND.

The gold output of New Zealand for July amounted to 25,838 ounces, of the value of £98,237, as compared with 17,891 ounces, value £68,711, in July of '98.

The director of the Thames School of Mines has reported the discovery of sulphide of molybdenum within the area of the Thames gold field, in Ohio creek, by W. Martin, Mgr. of the Iron Cap mine.

ONTARIO.

It is reported a new mining district has been found east of Mine Center, Ontario. The veins are gold-bearing quartz.

The Sultana mine has been sold to the British Capital Corporation, Ltd. The mine has been the property of J. F. Caldwell, who developed the property to its present condition. The mine comprises seventy acres, with a vein 30 feet wide on the surface and running $7 to the ton gold. Its gross output for three years, with a 10-stamp mill, averaged $3000 per month. A 30-stamp mill was put in last fall.

SOUTH AFRICA.

Diamonds are being found in a number of new localities at Kimberly and Pretoria. A third pipe has been found at the new Schuler mines.

London *Mining Journal*: The shaft of the Cinderella Deep at Boksburg has reached a depth of 200 feet. The borehole which is being put down in front of the shaft has attained a depth of over 1000 feet.——The Pretoria diamond fields continue to attract attention, and now that washing operations have been resumed at the Schuller mine some idea of its value may be obtained. During the month of June this mine returned 570 carats, Elandshoek 1500 carats, and Byenestpoort 415 carats.——The New Primrose July production was 10,762 ounces; profit, £16,073; 160 stamps, 28 days.——The Robinson Deep reports Aug. 9 for July: Crushed 15,505 tons; obtained 6103 ounces of gold from mill, 3393 ounces from tailings by cyanide, 506 ounces from slimes; total, 10,002 ounces; profit for the month, £10,000.——Jumpers Deep reports results for July: Number of days working 100 stamps, 29 days 15 hours; tons crushed, 15,787; yield in gold from mill, 4270 ounces; tons of sands and concentrates treated by cyanide, 11,490; yield in gold, 3117 ounces; tons of slimes treated, 4050; yield in gold, 371 ounces; total yield in bullion, 8763 ounces, equal to 7758 ounces fine gold; estimated profit for month, £9100.——Simmer & Jack Proprietary during July crushed 45,000 tons, obtained 13,578 ounces of gold from mill, 7908 ounces from tailings cyanide, and 786 ounces from slimes; total 22,272 ounces; profit for the month, £32,268 10s.——Langlaate Estate and Gold reports production for July: Stamps running, 200 for 25 days, owing to lack of labor; ore crushed, 25,333 tons; gold retorted, 5776 ounces; tailings, cyanide process, 15,750 tons; gold recovered, 2470 ounces; concentrates, cyanide process, 591 tons; gold recovered, 1772 ounces; total gold recovered, 10,018 ounces.——The Langlaate Star Gold reports production for July as follows: Stamps running, 60 for 27 days, owing to lack of labor; ore crushed, 7780 tons; gold retorted, 1810 ounces; tailings, cyanide process, 6340 tons; gold recovered, 578 ounces; concentrates, cyanide process, 65 tons; gold recovered, 132 ounces; total gold recovered, 2520 ounces.

THE YUKON.

Dawson reports hydraulicking operations in progress on Bonanza creek. Pulver & Pellitier are operating a duplex pump throwing a 5-inch stream of water against a point of hill near claims 61 and 62 below on Bonanza.

Pay dirt has been discovered high up on points jutting out into Bonanza valley, above tiers of bench claims. The pay runs from 15 to 40 cents per pan. All are being sluiced.

Recently Declared Mining Dividends.

Empire State, Idaho, M. Co., Wardner, Idaho, $19,703; Aug. 20.

Creston Leasing Co., working the Jack Pot mine, Cripple Creek, Colo., $80,533.80; Aug. 30.

Pennsylvania M. Co., Nevada Co., Cal., 20 cents per share; Aug. 25.

Industrial Notes.

—In every line is at present found a sellers' market.

—An advance of 5% in the price of cold rolled steel shafting is reported.

—The New Zealand Government will join in defraying the cost of the proposed Pacific cable.

—The Standard Electric Co. is running a line for power between Stockton and San Francisco, Cal.

—Crushed linseed oil has been advanced to 40 cents a gallon by the two companies controlling the output.

—Trinity Co., Cal., placer mine owners are paying $2 a day and board and lodging to pick and shovel men.

—Barstow, Cal., is to be made division headquarters for the Santa Fe. The shops now at San Bernardino will be moved.

—Smelter preferred and railroad stocks have advanced several points since the cessation of the Colorado smelter strike.

—To carry out its proposed works the Kootenay Railway & Navigation Co. of Kaslo, B. C., has arranged a 5% mortgage for $2,400,000.

—The Butte County, Cal., Electric Power & Lighting Co. has a contract to furnish power to Chico and Oroville and to dredgers on Feather river.

—The Colorado Fuel & Iron Co. is building the Crystal River Railway, and have 200 men grading and laying track between Redstone and Marble, Colo.

—Tampico, State of Tamaulipas, Mexico, is to build a water works and sewerage system. Consul Magill, at Tampico, advises contractors to write to him for details.

—The Virginia *Chronicle* figures out that the Floriston, Cal., Co. will make 55% on the investment in the power plant to furnish the Comstock mines with electric power.

—The Southern Pacific Co. is replacing its twenty-ton coal cars with cars that carry 100,000 pounds. The coal is unloaded from these cars by two chutes, one on each side.

—A telegraph line from Umtali to Tete in South Africa, 1000 miles in length, has recently been completed, by means of which Nyassaland is brought into communication with the outside world.

—Orders have been received by Mgr. Merriman of the American Steel Co. at Everett, Wash., to send the nail machines there to San Francisco, to be used in enlarging the nail mill operated by the company.

—A mortgage for $100,000,000, issued by the Central Pacific Co. to the Central Trust Co., is being filed in the counties of California through which the road runs. The mortgage requires $50,000 worth of revenue stamps.

—Bradstreets estimates that the recent smelters' strike in Colorado resulted in a loss of $10,000,000, divided among the smelters themselves, their employes, miners, coke burners, rock breakers in the limestone quarries and the railroad lines.

—Burlington officials are reported negotiating for the purchase of the Denver, Lakewood & Golden road, a suburban line twenty miles long, owning valuable terminals in Denver and Golden, Colo., as well as a right of way through the mountains for a Salt Lake, Utah, short line.

—The Yuba, Cal., Power Co.'s sixty-four-mile line to Sacramento is completed. It furnishes the greatest voltage of any Western electric company, with the exception of the Provo-Mercur Co. of Utah. The 5000 H. P. to Folsom will be conducted over the wires at a loss of less than 10%.

—The directors of the Union Pacific will increase the company's capital stock to absorb the Oregon Railway & Navigation Co. and Oregon Short Line, the exclusive ownership of the entire line operated by the Union Pacific from the Missouri river at Omaha and Kansas City to Portland being thus vested in the Union Pacific.

—The California State Fair begins at Sacramento on the 4th inst. and continues to the 16th inst., and this year offers unusual attractions to exhibitors and visitors. The great race horse "Ormonde" will be on exhibition at the State Fair. This is one of the most famous horses in the world, and will be an object of great interest.

—H. M. Whitney in Cape Breton will sink a shaft which is to have a daily capacity of 4000 tons of coal, and will command 55,000,000 tons. The acquisition of one-half of the Belle Isle, Newfoundland, iron fields has been completed by representatives of the Whitney syndicate paying over $1,000,000. The contract for 400 coke ovens has been given to the United States Gas & Coke Co. of Philadelphia for $1,000,000.

—The Trans-Andine railway line, which is expected to connect the Pacific with the Atlantic, from Valparaiso, Chili, to Buenos Ayres, Argentina, lacks but forty-six miles of completion. Recent appropriations for completing the tunnels required for this purpose encourage the belief that it will soon be completed, and through land transportation thus given between the Pacific and the Atlantic at that point.

—The American-China Development Co. and the British-Chinese Corporation of London and Shanghai have agreed to consolidate in the formation of an Anglo-American syndicate to carry on various projects in China, notably building railways and developing gold and copper mines. The first work contemplated is the building of a railway from Shanghai to Canton, a distance of 700 miles. D. D. Mann is to have charge of the work.

—United States Consul Halstead at Birmingham, England, gives publicity to the belief that to those engaged in wheat-cornering operations in the United States is due the competitive opening up of vast areas of wheat land in Russia, India, South America and Egypt. The present corner in copper and resultant high price of that useful metal, he says, may result in injury to the copper-mining interests in the United States parallel to the loss caused to America by the corners in wheat.

—Regarding the statement in this column last week that "the War Department will soon buy 40,000 horses," which has been questioned, the facts are in exact accordance therewith. Government agents are now traversing the country buying suitable horses and sending them in for government shipment. The Pacific section will get about one-half the number stated. Lieut. Horne of the Ninth Cavalry, U. S. A., is doing the buying for the Pacific coast. He is now in Ogden, Utah. He buys the biggest animals he can get and sends them in lots of 200 to the quartermaster at San Francisco who sends them to Manila.

List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey, Strong & Co., Pioneer Patent Solicitors for Pacific Coast.

FOR WEEK ENDING AUGUST 22, 1899.

631,414.—FURNACE—J. A. Anker, Los Angeles, Cal.
631,692.—CAR WHEEL—J. W. Breeding, Bisbee, A. T.
631,693.—CAR AXLE BOX—J. W. Breeding, Bisbee, A. T.
631,620.—CORSET—R. Cousins, S. F.
631,710.—ELEVATOR—E. M. Fraser, S. F.
631,399.—GUN BARREL—H. P. Gillette, Roseburg, Or.
631,712.—ROCK DRILL—W. Gleeson, Unga, Alaska.
631,506.—NUT LOCK—J. Jorgenson, S. F.
631,507.—POLISHING ROLL—E. Kelly, S. F.
631,526.—DRAPER SLAT PROTECTOR—C. J. and T. T. Luckehe, Gridley, Cal.
631,431.—LOCK—P. Phelps, Seattle, Wash.
631,432.—LOCK—P. Phelps, Seattle, Wash.
631,433.—LOCK—P. Phelps, Seattle, Wash.
631,434.—LOCK—P. Phelps, Seattle, Wash.
631,443.—DOG HARNESS—B. A. Sammann, S. F.
631,477.—WAGON TRUCK—H. B. Schindler, Oakland, Cal.
631,680.—MINERAL EXTRACTOR—K. Staahlgren, Salinas, Cal.
631,535.—TAPPET—G. W. Waitt, S. F.
631,492.—SHAKE REGULATOR—R. G. Williams, Stockton, Cal.
631,602.—HAMMOCK SUPPORT—Wood & Taitt, Prescott, A. T.

NOTE.—Plain and Certified Copies of U. S. and Foreign patents obtained by Dewey, Strong&Co., by mail or telegraphic order. American and Foreign patents secured, and general patent business transacted with perfect security, at reasonable rates, and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey, Strong & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

DRAPER SLAT PROTECTOR.—C. J. and T. T. Luckehe, Gridley station, Cal. No. 631,526. Dated Aug. 22, 1899. This invention relates to a device for protecting the transverse slats of canvas and for carrying belts commonly known as drapers, and to provide a means for readily removing broken slats and introducing new ones without removing the protecting portions. It consists of a canvas belt having leather straps extending along the edges and central portions of the belt in the direction of its travel, transverse slats extending across the top of the belt at intervals having the ends secured through the edges of the belt and through the straps beneath. Metal caps are fitted over the top, sides and ends of the slats, with bendable tongues and pins by which they are removably locked to the slats. Loops or keepers are fitted over the slats intermediate between the ends so that the slats can be slid through the loops to put them in place or remove them. These loops are riveted upon the central portion of the belt or these straps which pass beneath.

ELEVATOR.—E. M. Fraser, San Francisco, Cal. No. 631,710. Dated Aug. 22, 1899. This invention is designed to provide a means for automatically maintaining any desired tension upon the endless traveling ropes or cables by which the raising and lowering of the cage and connected parts are effected. The tension device is automatically operating. The rope passing from the car over a pulley is counterweighted at the opposite end, and guides are formed upon the counterweight. A second counterweight is slidable upon these guides, a rope passing from it over a pulley, and thence to a movable frame. In combination with these are independently actuated driving pulleys, with an endless rope or cable thereon and pulleys upon the main counterweight and the frame around which the said rope or cable passes.

NUT LOCKING DEVICE.—J. Jorgenson, San Francisco, Cal. No. 631,506. Dated Aug. 22, 1899. The object of this invention is to provide a means for locking nuts upon the ends of axles or shafts or for other like purposes. It consists essentially in the combination with a nut having a slot made in the outer end and a spring pressed lever fulcrumed to one side of the nut, having the outer end diagonally beveled, and an axle or shaft, the end of which has V-shaped locking notches formed in the angle of the end in such a manner that the locking takes place from the end and side. In connection with this is a latch lever to engage the locking notches in the spindle end, and the long arm is tapered and extends around the side of the nut. A spring acts to normally force this end of the arm of the lever outwardly to cause the latch to engage with the notches of the spindle. This arm will be depressed whenever a wrench is placed upon the nut, thus disengaging the opposite end from the notches preliminary to turning the nut by the movement of the wrench, and when thus disengaged the nut can be easily removed.

Personal.

THOS. EWING of the Arizona & New England M. Co. is in Kingman, Ariz.

JAS. H. BARRY has taken charge of the Jessie mine, Breckenridge, Colo.

J. B. FRANK has charge of the cyanide plant at Camas No. 2, Hailey, Idaho.

F. H. DAKIN, JR., is chemist at the De Lamar mines, Copper City, Cal.

JNO. J. LAWRENCE is the new Supt. of the Conlan mine, Grass Valley, Cal.

T. A. RICKARD has returned to Cripple Creek, Colo., from an Eastern trip.

ALBERT BURCH is now Supt. of the Bunker Hill & Sullivan at Wardner, Idaho.

SUPT. BASSETT of Los Angeles has charge of the Kenton mine, Alleghany, Cal.

JNO. B. RULE is the new foreman at the Boston Group, Gold Creek, Juneau, Alaska.

A. R. WILFLEY, the inventor of the Wilfley concentrator, is visiting Cripple Creek, Colo.

JOS. R. RYAN succeeds G. McM. Ross as Supt. of the Comstock Pumping Association.

JNO. BRADBURY of Los Angeles, Cal., is examining mining property at Mazatlan, Mexico.

GEO. E. WOODBURY of San Francisco, Cal., has returned from a business trip to Denver, Colo.

F. M. JOHNSON takes the place of E. A. Powers as Supt. Cochiti G. M. Co., Bland, New Mexico.

THOS. CLARK, a prominent member of the El Dorado, Cal., County Miners' Association, is in San Francisco.

DR. PFLEUGER, the noted German geologist, is in San Francisco, Cal., circling the globe for the fourth time.

ARTHUR WARREN, of the Westinghouse Electric & Mfg. Co., has returned to New York City from Europe.

T. B. DILLON has returned to San Francisco, Cal., from an examination of the mines of El Dorado canyon, Nevada.

E. H. BENJAMIN, Sec'y Cal. State Miners' Association, has returned to San Francisco from El Dorado Co., Cal.

J. S. COXEY, of Commonweal army fame, is at the head of a company that has opened a lead mine at Joplin, Mo.

F. MURPHY, a South African mining engineer, is examining a copper property at Sodaville, Esmeralda Co., Nev.

A. E. VANDERCOOK, Supt. of the cyanide plant at El Dorado canyon, Nevada, is in San Francisco, Cal., on business.

JOHN W. MACKAY arrived in San Francisco from New York City on the 28th, and will remain in California some weeks.

KARL PETERS was at Unyango, South Africa, Aug. 1st, '99. He reports the discovery of an ancient gold mine at Mt. Swia.

W. H. HONNOLD, late Supt. and Mgr. Thorpe G. M. Syndicate, Calaveras Co., Cal., is examining copper properties in Arizona.

JOSEPH BROWN has been appointed Supt. of the White Hills M. Co.'s property in Mojave Co., Ariz., succeeding W. A. Robinson.

FRANK C. ROBBINS of Greenwood, B. C., has been appointed consulting engineer for the North Star M. Co. at Fort Steele, B. C.

J. P. CHANNING, a mining engineer of New York, and B. B. Knobenhauer are at Virginia City, Nev., guests of Prof. F. E. Fielding.

PROF. S. F. EMMONS of the U. S. Geological Survey is in Butte, Montana, completing a report on the economic geology of that district.

WM. MCDERMOTT, who recently bonded the Afterthought and other copper properties in Shasta Co., Cal., has returned to Salt Lake, Utah.

W. J. ADAMS has returned to San Francisco, Cal., from a visit to Mariposa county mines, and has gone to Jackson, Cal., to examine the Kruger and Vaughn.

T. H. OXNAM, till recently manager DeLamar, Nev., G. M. Co., is in Los Angeles, Cal., with a view to interesting English capital in mining investments.

PROF. AGASSIZ sailed from San Francisco, Cal., for the South Pacific last week with a party of scientists on the steamer Albatross for a six months' trip of exploration.

C. H. LINDLEY has returned to San Francisco from Harqua Hala, Ariz., where he sold the famous mine of that name to its original owner, as related in the issue of Aug. 19th.

W. B. STOREY, JR., formerly assistant engineer U. S. Debris Commission, has been appointed chief engineer Santa Fe Railroad system, with headquarters at Topeka, Kan.

COL. D. H. JACKSON, present Supt. Darling mine, will have charge of the work on the Gopher, Boulder and Dalmatia mines, Kelsey, El Dorado Co., Cal., recently bought by English parties.

JOHN B. FARISH, E. M., of Denver, Colo., is at present in Mexico. He will return to the United States and make an examination of the Heath district in Idaho, between Weiser and Seven Devils.

DUNCAN MCVICHIE, Gen. Supt. De Lamar's Mercur mines, accompanied by H. H. Greene, has gone to prospect the Heath district, Idaho, which begins fifty miles north of Weiser and is between that camp and the Seven Devils country.

W. A. PRICHARD has been appointed Mgr. of the Keystone Con. Mines at Amador City, Cal. The Keystone property is one of the largest gold producers on the mother lode, its total production to date having passed the $15,000,000 mark. Mr. Prichard was formerly connected with the U. S. Geological Survey, and is a graduate of Stanford University.

V. C. HEIKES, Honorary Special Agent of the Department of Mines and Metallurgy for the Commissioner General of the United States to the Paris Exposition, has gone from Arizona to New Mexico in his quest for mineral exhibits.

G. McM. ROSS, who recently resigned the superintendency of the Comstock Pumping Association, is credited with intention to resume direct control of the Empire copper property at Copperopolis, Cal., which he was recently instrumental in selling to the Ames estate of Boston.

Commercial Paragraphs.

THE Edward P. Allis Co. of Milwaukee has a contract to supply five vertical cylinder blowing engines, aggregating 500 H. P., for the Dominion Steel Co.'s blast furnaces at Cape Breton, Canada. The Allis Co. has also been awarded the contract for engines to supply electrical power for the Glasgow, Scotland, tramway. The contract price for the latter was £114,544.

"LOWER CALIFORNIA ILLUSTRATED"—*Baja California Illustrado*—is the title of a finely bound and superbly printed book now being compiled by Col. J. R. Southworth, 23-25 First St., San Francisco, the first publication on Lower California ever published. An official map of the entire peninsula accompanies the publication, which is devoted to the mining, agricultural, industrial and commercial interests of that region.

WM. AINSWORTH & SONS of Denver, Colo., under date of Aug. 24 write that after Sept. 1st, '99, the discount on button balances of their manufacture will be increased to 25%, and on pulp and chemical balances to 15% from Catalogue "A" list. They say: "This reduction is made possible by the modern equipment of our factory for the manufacture of balances, and by the decreased cost of manufacture and excelling facilities we now have for placing our product in the markets of the world. Although the reductions in prices of our balances will make them as cheap as inferior instruments, their high standard will be maintained and our reputation as makers of the most accurate assay balances shall never be questioned. We are now prepared to furnish balances for scientific purposes, sensitive to 1-1000 milligramme, under full guarantee."

FRASER & CHALMERS have issued in pamphlet form the recent decision by Federal Judge Moses Hallett in the Circuit Court district of Colorado, affirming the validity of the U. S. letters patent granted to Horace F. Brown for improvements in the construction of ore roasting furnaces. The case in question is No. 3508, a bill to restrain infringement of patent, Horace F. Brown, plaintiff, the Metallic Extraction Company, defendant, the decree issued July 31st, '99, being wholly in favor of plaintiff. In his decision of July 28th, '99, Judge Hallett concludes: "I suppose there will be a decree for an accounting in the first instance. If an injunction is desired and respondent will agree to pay what shall be regarded as a reasonable royalty at the end of the suit, no injunction will be issued. The furnaces which are being used by the respondent are, it appears, in somewhat general use in different parts of the country, and the question as to infringement has been a matter of some doubt. Of course, the case is to be reviewed in the Court of Appeals, and until that shall occur and the rights of the parties are finally settled by a decision in that court, I should think it unreasonable to restrain the use of the furnaces which have been put up by the respondent."

INCREASING business and the consequent necessity for better quarters occasion the removal of the San Francisco Plating Works from 653 and 655 Mission street, San Francisco, to 652 Mission street, corner Annie, opposite their present place of business. The removal of such an old and prominent establishment is worthy of more than passing notice. Reference to the old files of this paper shows that more than twenty years ago the advertisement of the "San Francisco Plating Works, E. G. Denniston, Proprietor," appeared in these columns, and, through the years, the announcement with the familiar "653-655 Mission street" has steadily appeared in every issue. So firmly is this number fixed in the minds of Mr. Denniston's many patrons that it will require a little effort to remember that it is no longer "653-655;" but, as the works are simply going across the street, it will not be long before the new number will be as familiar as the old. Twenty years in San Francisco mercantile life is a long span, and Mr. Denniston, the energetic proprietor of the San Francisco Plating Works, is to be congratulated upon his well-merited success. Many of the largest mills in the country have recognized the advantage of silver-plated copper plates and the fine character of those furnished by Mr. Denniston's establishment. In manufacturing his silver-plated copper plates he uses only the best annealed Lake copper and refined silver. This point is of value to mill men who may find difficulty in saving gold on raw copper plates because of its fineness, or for other reasons.

Catalogues Received.

THE Jackson Drill & Mfg. Co., 1756 Larimer St., Denver, Colo., issue an illustrated pamphlet with halftone and sectional views of the Jackson drill, and special information of interest to any miner who wants some points as to a hand power drill. On the principle that a pleased customer is a good advertisement are given testimonials from miners who have used the drills and a list of recent purchasers of the Jackson hand power rock drill is appended.

Average Life of an Iron or Steel Bridge.

The estimate of the length of life of steel bridges is altogether too limited. The permanence of a steel bridge will depend upon three conditions—the design, the loading, and the maintenance. If it be properly designed for a specified maximum loading; if oversight be exercised that this loading is never exceeded, and if the steel work is thoroughly accessible and painted at regular intervals, there is no reason why a bridge should not last for centuries. As a matter of fact, however, these conditions are too often ignored or imperfectly fulfilled. In the first place, although bridge designing should always be intrusted to a specialist, even if the structure is to cost no more than $50,000, many county bridges and those constructed in smaller towns are built from the designs (so called) of the local surveyor, who may have the vaguest ideas of the strains to which the various parts are to be subjected and the best way to proportion the different members and connect them into a finished structure. The construction also should always be carried out by a recognized bridge firm, for the local blacksmith or machinist's shop is usually no more fitted for building good bridges than it is for building lathes and locomotives. It is questionable whether amateur bridge building can produce a structure with a useful life of twenty-five years.

To secure the best results the county officers, board of aldermen, or whoever it is that has the matter in hand, should first determine exactly what uses the bridge is to be put to, and the greatest possible loading to which it will be subjected. This information, together with the location and other data, should then be published for the benefit of the competing bridge companies, who should be given a free hand as to the style of structure best adapted to the case. In this way a better and a cheaper bridge will be secured, even in the case of insignificant structures, whose construction it might be supposed the bridge companies would not be at the trouble to undertake. When such a bridge is completed the question of its life will be one of care and maintenance. If every inch of the steel work receives a periodical coat of the best non-corrosive paint, and care is taken that the bridge is not strained beyond the limit agreed upon when it was designed, it will probably outlast its usefulness. The popular belief that a subtle process of crystallization is slowly weakening the metal of all the bridges is a fiction, pure and simple. The metal can only lose its life when it is strained beyond its elastic limit, and so long as the designed loading is not exceeded this contingency can never happen.—Iron and Steel.

America Leads as a Producer of Iron and Steel.

The following shows the quantity and the percentage of the production of iron and steel by each of the important producing countries for the latest available years, the quantities being expressed in gross tons of 2240 pounds for Great Britain, United States and Canada, and the metric ton of 2204 pounds for all other countries:

Countries.	Year.	Tons.	Per cent.
United States	1898	11,773,934	33 02
Great Britain	1898	8,631,151	24 21
Germany and Luxemburg	1898	7,232,988	20 29
France	1898	2,534,427	7 11
Belgium	1898	979,101	2 75
Austria and Hungary	1897	1,308,493	3 67
Russia and Finland	1898	2,193,750	6 15
Sweden	1897	539,197	1 51
Spain	1898	261,700	.73
Italy	1897	8,393	.02
Canada	1898	68,755	.19
Other countries	1897	125,000	.35
Total		35,655,088	100.00

The production of steel for the same countries upon the same basis was as follows:

Countries.	Year.	Tons.	Per cent.
United States	1898	8,932,857	37.02
Great Britain	1898	4,665,986	19 33
Germany and Luxemburg	1898	5,779,570	23 96
France	1898	1,473,100	6.11
Belgium	1898	653,130	2 71
Austria and Hungary	1896	880,696	3 65
Russia and Finland	1897	1,153,000	4.78
Sweden	1897	275,128	1.14
Spain	1898	213,015	.88
Italy	1897	63,940	.27
Canada	1898	21,540	.09
Other countries	1897	15,000	.06
Total		24,126,962	100.00

Ten years ago the United States produced 30% of the world's pig iron and Great Britain made 33%. Twenty years ago the percentages were 16 and 45 respectively.

W. R. DUDLEY, professor of botany in Stanford University, speaking of the sequoia of the Sierra and their distribution, says the sequoias of California represent a type of tree found nowhere else. Were it not for the high mountains of California there would be no forest except in the fog belt along the northern coast; consequently there would be no summer flow in the rivers and the State would be largely a desert, instead of being possessed of great fertility. The Pacific coast, on account of its variety of climate, is the home of a large number of conifers that are extremely rare in other parts of the country. These forests deserve protection and particular care on account of the rare types, of interest to science, which they contain, aside from all questions of commercial utility.

The Largest Vessel Afloat.

The new White Star liner Oceanic, expected to arrive at New York this week, is 704 feet long, 68 feet beam and 44 feet depth of hold; gross measurement, a little over 17,000 tons, or about 5000 tons larger than the Cunard line vessels, Campania and Lucania, which have held the record for size on the New York and Liverpool route. Her cost is over $5,000,000. The following table illustrates some features of the development of large shipbuilding during the past forty-one years:

Names.	Year.	Length, ft. in.	Breadth, ft. in.	Depth, ft. in.	Displacement, Tons.
Great Eastern	1858	680	83	57–6	27,000
Britannic	1874	455	45	36	8,500
Arizonia	1879	450	45–2	37–6	.....
Servia	1881	515	52	40–6	9,000
Alaska	1881	500	50	39–8	.....
City of Rome	1881	542–5	52	38–9	11,380
Oregon	1883	500	54	40	.....
Paris	1888	527–6	63	41–10	13,000
Teutonic	1890	565	57–6	42–2	12,000
Campania	1893	600	65	41–6	.....
Kaiser Wilhelm der Grosse	1897	625	66	[illegible]	20,000
Oceanic	1899	704	68	[illegible]	28,500

The Oceanic will have accommodations for 1710 passengers and will carry a crew of 390 men.

"GIANT" SHOES AND DIES.

Made of hammered steel, forged and hardened by special process.
These shoes and dies are made in San Francisco and can be furnished within a week after receipt of order.

THE COMPRESSED AIR MACHINERY CO.,
11-13 FIRST STREET, SAN FRANCISCO, CAL.

SELBY SMELTING AND LEAD CO.,

REFINERS OF GOLD AND SILVER BARS, GOLD DUST, ETC.

Buyers of Gold, Silver, Lead and Copper Ores, Gold Concentrates, Lead Bullion, Cyanide Product, Etc.

ORE AND BULLION ASSAYERS.

Works at VALLEJO JUNCTION, CAL. Office, 416 MONTGOMERY ST., SAN FRANCISCO, CAL.

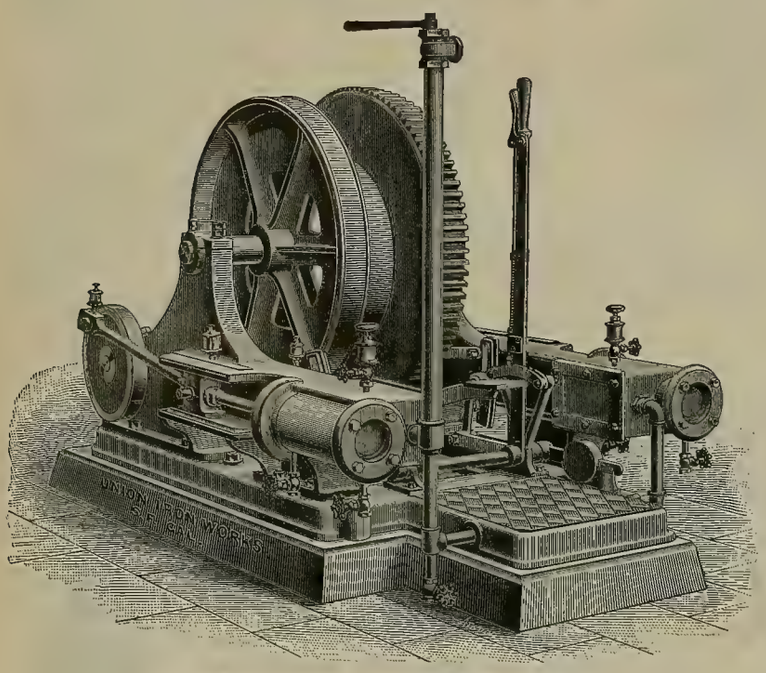
TYPE "C" INDUCTION MOTOR OPERATING MINE HOIST.

Westinghouse Induction Motors

The most economic motor for mine service.

Westinghouse Electric & Mfg. Co.,
PITTSBURG, PA.
Mills Building, San Francisco.

All Principal Cities in U. S. and Canada and Foreign Countries.



93C-2

UNION IRON WORKS,

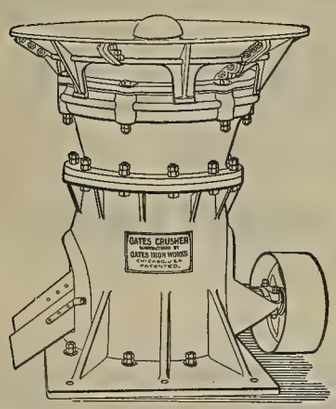
222 Market Street, San Francisco, Cal.

MAKE THIS SMALL

DOUBLE CYLINDER SINGLE DRUM HOIST

HOIST FOR PROSPECTING.

For Prospecting Purposes or Underground Work,



USING COMPRESSED AIR.

The entire hoist is self-contained, being mounted on an iron sole plate or bed which carries all the operating levers and provides a footboard for the operator. The engines are provided with reversible link motion and the drum with a broad strap brake, insuring safe and rapid work.

The general lines upon which this hoist is designed are neat, strong and substantial and all the operating parts are conveniently arranged.

The size herewith illustrated is the 4 in. x 10 in., rated at 15 horse power. The larger sizes, 8 in. x 12 in. and upwards are provided with post brakes.

GATES IRON WORKS.

The Original GYRATORY BREAKER.

It is ADJUSTABLE, and INDESTRUCTIBLE.

THERE ARE 4,000 OF THEM IN USE.

The South African Mines Have Purchased 200.

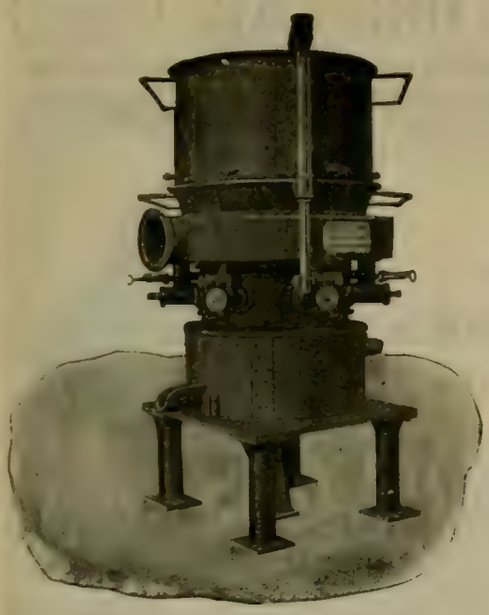
. . We build a FINE CRUSHER that is a wonder. . We know how to design this class of machinery. . . . There are others who think they know how to make a Gyratory Crusher; they are simply poor imitators of The Only Great Gates Rock and Ore Breaker. .

Address for Catalogue No. 1, Dept. UU, 650 Elston Ave., CHICAGO.

J. FURTH, President. I. HULME, Manager. H. P. STRICKLAND, Secretary. R. V. ANKENY, Treasurer.

THE VULCAN IRON WORKS COMPANY,

SEATTLE, WASH.



Iron and Brass Founders, Machinists and Blacksmiths.

MANUFACTURERS OF ALL CLASSES OF MACHINERY.

Mining Machinery and Engine Building

A SPECIALTY.

The most modern, completely equipped and up-to-date plant in the Northwest. Everything new from end to end.

A MODERN COPPER SMELTER (ROUND FORM).

THE COLORADO IRON WORKS CO.,

Established 1860. DENVER, COLO.

MANUFACTURERS OF

Smelting Furnaces and Equipments

For the Treatment of

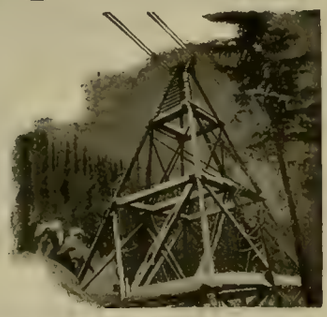
GOLD, SILVER, LEAD, COPPER and PYRITIC ORES.

THIS CLASS OF WORK IS A SPECIALTY WITH US.

We also manufacture all kinds of Ore Milling Equipments for Amalgamation, Concentration, Cyanide and Chlorination Processes.

(SEE PAGE 273.)

THE MINE AND SMELTER SUPPLY CO.,



DENVER, - - COLORADO.

Mining and Milling Machinery and Supplies.

We beg to call your attention to

THE FINLAYSON PATENT WIRE ROPE TRAMWAY—

the latest and best system of double-rope automatic aerial tramway in the market.
If interested in the most economical system of transporting ores from mine to mill and to shipping stations, send for our special tramway catalogue.

We carry a complete stock of Machinery and Supplies for immediate delivery.

Send for our special catalogues on Mining Machinery, Milling Machinery, Wilfley Concentrators, Tramways, Power Transmission Machinery, Etc.

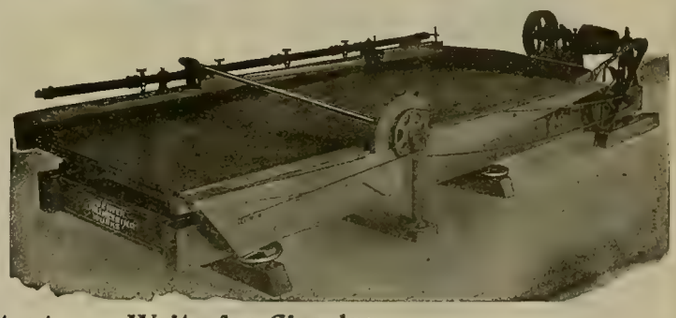
No. 16 San Francisco St., City of Mexico.



BOILERS, ENGINES, STEAM HOISTERS, ELECTRIC HOISTERS, ROLLS, CRUSHERS, WILFLEY TABLES, CARS, CAGES, ORE BUCKETS, RAIL, PIPE, FITTINGS, BELTING, ETC., ETC.

THE : CAMMETT : CONCENTRATOR.

Designed with some Regard for the Laws of Concentration.

The perfect vanner motion given to the pulp by our head motion, together with the freedom from "jumping" resulting from the special rigid guides used, explains why the Cammett riffles never "pack," and why the table has such a great capacity when handling slimes. : : : : : : : : : : : : : : : : :

The continuous grooves and riffles extending from end to end of the table maintains the greatest possible margin of safety between the concentrates discharge and the tailings. : : : : : :

Thoroughly Protected by Strong Patents. Write for Circular.

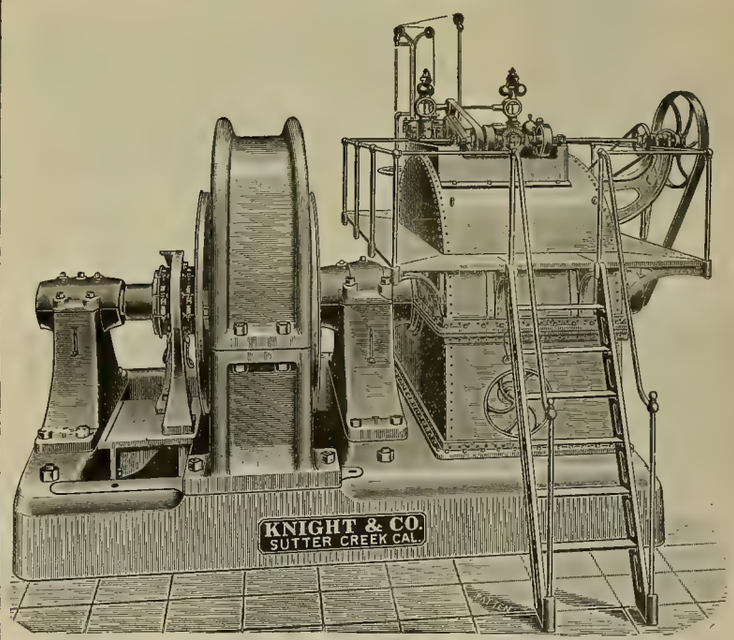
WILFLEY CONCENTRATOR.

The Wilfley Table is fully covered by U. S. patents Nos. 580,338 and 590,675. Infringements will be prosecuted to the full extent of the law.

PRICE, $450, F. O. B., San Francisco.

One of these machines will take the place of two or three belt concentrators of any style and do very much better work. Easy adjustment. Little wear.



Some Practical Reasons Why the Wilfley Concentrator Should Be Used in Gold Mills:

1. It will successfully handle three or four times more material than any belt Concentrator made, without exception.
2. It will save more sulphurets in proportion while so doing, and catch any float gold, amalgam or quicksilver which may escape from mortars or plates.
3. It will make cleaner and much more valuable concentrates, thus saving useless expense for transporting valueless material, as also extra cost for treatment.
4. It requires little or no attention when once adjusted and no expert is required to either adjust or run the machine.
5. It will save much expense in power and room, and the first cost of a mill requiring concentrators.
6. It has no expensive belts to crack and wear out, nor complicated machinery to keep in repair.
7. It is the only sensible plan of concentration, as any kind of material can be worked, which is not true of any style of belt machine.

—— SEND FOR CIRCULARS. ——

These Machines are Kept in Stock Ready for Immediate Shipment.

KNIGHT'S WATER WHEEL.

The accompanying cut shows the general arrangement of **The Knight Water Wheel**, direct coupled to a 750 kilowatt generator, with governor mounted on top of wheel casing.

MINE BELL SIGNALS.

Adopted, Used and in Force in Accordance with Law.

We print in legal size, 12x36 inches, the Mine Bell Signals and Rules provided for in the Voorhies Act passed by the California Legislature. The law is entitled "An Act to Establish a Uniform System of Bell Signals to Be Used in All Mines Operated in the State of California, for the Protection of Miners." We furnish these Signals and Rules, printed on cloth so as to withstand dampness. 50 Cents a Copy.

MINING AND SCIENTIFIC PRESS, 330 Market St., San Francisco, Cal.

THE IDEAL CONVEYOR BELT

Is the one that will carry stone, ore, coal, wet or dry material, holding buckets firmly and securely; will stand all kinds of exposure, and resist the heaviest strains during a long period of service. This is what the LEVIATHAN BELT has done, and we quote the following from a letter from the New York Steam Co.:

"We have used Leviathan Belting for four years, up to 24-inch by 8-ply, elevating and conveying coal. Some of the Belting is outside, exposed to freezing weather; some in a steam bath. In both conditions the results have been very gratifying, over 500 tons having been handled in ten hours time."

SPECIAL DEPARTMENT OF

Hydraulic Mining Machinery,

Comprising Hydraulic Gravel Elevators, Double-Jointed Ball-Bearing and Single-Jointed Giants, Sheet-Iron and Steel Water Pipe and Fittings, Water Gates, Etc.

NOTICE.—All other forms of Hydraulic Gravel Elevators are simply poor imitations in construction and infringements of the patents held by us.

The Double-Jointed Ball-Bearing Giants recently perfected and patented by our MR. JOHN H. HENDY are incontestibly superior to any other form of Giants yet introduced.

We are prepared to furnish plans and estimates of cost of any proposed Hydraulic Mining Plants upon any specifications submitted to us, and tender the services of our Hydraulic Mining Engineer to erect and place same in successful operation under guarantee.

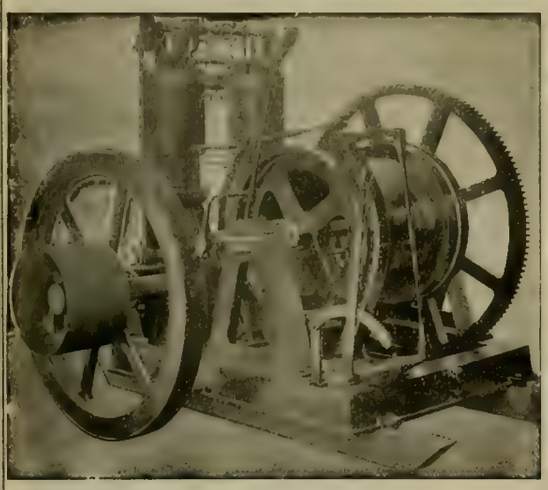
General Arrangement of Pelatan-Clerici Plant.

The "Pelatan-Clerici" Process



OF TREATING REFRACTORY ORES

Saves the precious metals by the simplest, most economical and most efficient process known. No roasting or previous treatment, except ordinary crushing. Extraction complete in from 6 to 12 hours. Extracts equally well both fine refractory gold and coarse gold in the form of amalgam. Makes a greater saving of gold than any other process from raw material at less cost. The electric current and dissolving agent promptly dissolve the precious metals, both gold and silver. Samples of ore tested free of charge. Several mills saving over 90 per cent of values by bullion returns. Simplicity. Economy. Efficiency.

P&B
BUILDING PAPER

The walls of a house are built for protection. If the sun and weather open up the sheathing, the rain or the air will get in and cause discomfort and doctor's bills. To prevent this the architect or builder uses building paper. There are many kinds, but only two classes—the poor and the good. P & B PAPER is good—the best. It is very strong, odorless, waterproof and airproof, and will not rot. Ask your dealer for samples, or write us for them. We are the makers.

Market Reports.

SAN FRANCISCO, Aug. 31, 1899.

SILVER.—London, 27 3-16d; New York, 59 1-16; San Francisco, 59 1-16; Mexican Dollars, 49¼@50; New York exchange, sight, 10; telegraphic, 12½ cents premium.

LEAD.—New York reports quiet, $4.60 bid, $4.62½ asked; brokers' price, $4.35.
Local, pipe, 7¼@7½c; sheet, 7¼@8¼c; pig, 6¾c; bar, 6½c.
The National Lead Co. has advanced the price of white lead, red lead and litharge to the basis of 6c per pound in 500-pound lots and over.

COPPER.—New York reports Lake unchanged at $18.50; brokers' price, $18.75. Local—Mill copper plates, 23½c.
Copper remains unchanged, though there is an upward tendency in the American market. The English market is strenuously opposing any advance. It has been reported during the week that another strong syndicate is arranging to still further control the leading copper mines of the world, absorbing the Amalgamated Association, but these rumors have not affected the market.

IRON.—American, soft, $22.50@24.50 per ton; Scotch, $27.50 Local bar, 2¾c per lb.

STEEL.—11¼@20c per pound.

TIN.—Weak; $30.65 bid; 30.85 asked; pig, 36@39c per lb.
A slight decline in tin has been noticed the past two weeks. This metal is a favorite among English speculators, to whose manipulation the changes are largely due.

ANTIMONY.—In San Francisco 1000 pounds and upwards, 10c net; 300 to 500 pounds, 11@14c; less than 100 pounds, 15c.

BABBITT METAL.—No. 3, 8¾c.

QUICKSILVER.—Demand strong. Local, $45; export, $40.50@41; carload lots, special rates.
The quicksilver market has shown signs of rising value for some time past, but this is the first official announcement of an advance in price. No particular cause is assigned.

PLATINUM.—London, 63½s per ounce; York, $16.25; San Francisco, $16.75.

ALUMINUM.—N. Y. price, 26c.

Last year 5,200,000 pounds of aluminum, valued at $1,716,000, were produced in the United States. The value per pound was therefore 33 cents. In 1888 19,000 pounds of that metal were produced valued at nearly $3.33 a pound. This was for most purposes a practically prohibitory cost. But improved processess of manufacture reduced rapidly the market price of a metal that can be utilized in so many ways, and as a consequence there was a great increase in the output. The value per pound in 1889 was about $2.50, in 1890 $1, in 1891 66 cents, in 1894 57½ cents, in 1896 40 cents and in 1897 37¾ cents. The cost of production is being lowered, but not as rapidly as in earlier years. The slight reduction in 1898, as compared with 1897, was accompanied, however, by an increase of 30% in the output.

ASSAY LITHARGE.—100 lbs., 12c.

POWDER.—F. o. b. San Francisco: No. 1. 70% nitro-glycerine, per lb., in carload lots, 15¼c; less than one ton, 17¼c. No. 1*, 60%, carload lots, 13¼c; less than one ton, 15¼c, No. 1** 50%, carload lots, 11¼c; less than one ton, 13¾c. No. 2, 40%, carload lots, 10c; less than one ton, 12c. No. 2* 35%, carload lots, 9¼c; less than one ton, 11¼c. No. 2** 30%, carload lots, 9c; less than one ton, 11c. Black blasting powder in carload lots, minimum car 728 kegs, $1.50 per keg; less car lots, $2 per keg.

FUSE.—Triple tape, $5.10 per 1000 feet; double tape, $4.35; single tape, $3.45; Hemp, $8; Cement No. 2, $4.35; Cement No. 1, $3.45.

CAPS.—3x, $5.50 per 1000; 4x, $6.50; 5x, $8; Lion, $9.

CANDLES.—Electric Light Candles—6s, 16 oz., 8¼c; 6s, 14 oz., 7¼c; 6s, 12 oz., 5½c; 6s, 10 oz., 5½c; Granite (Mining) Candles—6s, 16 oz., 9¼c, 6s, 14 oz., 8¼c; 6s, 12 oz., 7¼c; 6s, 10 oz., 6¼c. Paraffine Wax Candles—1s, 2s, 4s, 6s, white, 10c; colored, 11c.

CHEMICALS.—Cyanide of potassium, jobbing, 32@33c per lb.; carloads, 29@30c; in 10-lb. tins 37c; sulphuric acid, 1¾c per lb. 66% B.; soda ash, $1.60 per 100 lbs. 58%; hyposulphite of soda, 2½@2¾c per lb.; blue vitriol, 5½@6c per lb.; borax, concentrated, 7@8c per lb.; chlorate of potash, 12@13c; roll sulphur, 6c; alum, $1.90@2.00; flour sulphur, French, 2¼@2½c; California refined, 1½@1¾c; nitric acid, in carboys 8c per lb; caustic soda, in drusm, 3@4c per lb.; Cal. s. soda, bbls., 65c; sks., 60c @ 100 lbs; chloride of lime, spot, 2.10@2.25c; nitrate of potash, in kegs, 8c; chlorate of potash, 25c; caustic potash, 10c in 40-lb. tins.

Types of Head Frames.

There is great diversity in the style of structures erected at the collars of mine shafts for the purpose of carrying the sheaves over which the cables pass from the cage, skip or bucket to the hoisting engines. The design must necessarily vary with the requirements. An inclined shaft requires a somewhat different type of frame from that suited to a vertical shaft, and shafts of different angles require variations in the head gear. Those who have seen only the great, massive timber frames found at most large mines, erected without regard to expense, braced and tied in most elaborate fashion; or those who have seen only the graceful steel frames which of late years are replacing the heavy timber frames, would doubtless form the opinion that all productive mines should be similarly equipped. Such, however, is not the case. Some mines which have produced large amounts of gold or silver have had the simplest equipment. On Fryer Hill, Leadville, Colo., some of the very rich ore bodies were raised to the surface by hoisting engines costing no more than $2000, the head frame consisting of a simple tripod—three stout poles disposed about the shaft and tied at the top, with a sheave wheel fixed near the apex. A more simple device can scarcely be imagined, yet a large amount of rich ore was hoisted from those early-day mines with devices of this description. It is true the workings were comparatively shallow, and these simple plants would not have proven efficient on the large, deep mines of Leadville to-day.

In the construction of gallows frames it is evident that an attempt is too often made to secure symmetrical proportions and strength without due regard to the strains to which these structures are subjected, with a consequent unnecessary extravagance in construction.

The accompanying illustrations show several of the types of head frames most commonly in use. The two-post gallows frame with the back diagonal braces is typical of the Cripple Creek district, Colo., and this style of frame is extensively in use there. It will be noticed that there are side braces to give it greater rigidity, the side swaying of this type of head gear making it necessary to frame it with much care and to tie it with strong iron rods.

HEAD FRAME, VAN ANDA, TEXADA ISLAND, B. C.

The four-post style of frame at the Van Anda mine, B. C., is much in use on the Pacific coast, and, while a strong frame, is too often built without due regard to the strains. The two-post frame is quite as good and is adapted to either vertical or inclined shafts. The Marble Bay head frame is after the modern type of steel frame and resembles in its construction that at the High Ore mine, Butte, Mont., designed by Geo. S. Binckley and described in the issue of the MINING AND SCIENTIFIC PRESS of July 22nd, '99. This style of frame embodies many of the best features of construction, as the timbers or steel columns and beams are disposed with direct reference to the strains.

GALLOWS FRAME, CRIPPLE CREEK, COLO.

HEAD FRAME, MARBLE BAY, B. C.—(MONTANA TYPE)

The head gear of the Oneida mine, Amador Co., Cal., designed by H. C. Behr, is one of the simplest types and withal the strongest frames in California. It has no superfluous timbers and each piece is placed in a position to resist and equally distribute the resultant strains when hoisting heavy loads rapidly from great depth, and when under heavy work shows scarcely a tremor.

In mines where the tonnage hoisted is not very large the trip rope and bucket are frequently employed, particularly when the mine is in the development stage. At Cripple Creek it is a common thing to find a two-post frame, like that illustrated on this page, provided with two horizontal timbers which are securely bolted to the vertical posts and back brace and extending beyond the shaft in front of the frame, the ends being joined by a heavy crosspiece, morticed and bolted to the extensions. This addition is made level with the cross-tie joining the two posts several feet below the sheave. Its purpose is to carry a trip rope in front of the shaft, and, if desired, another rope may be fastened to the tie joining the angle braces back of the shaft. By means of this arrangement ore may be dumped on one side of the shaft and waste on the other. This device saves much otherwise necessary sorting of ores.

HEAD GEAR ONEIDA MINE, AMADOR CO., CAL.

MINING AND SCIENTIFIC PRESS.

ESTABLISHED 1860.

Largest Circulation of any Mining Journal on the American Continent.

Office, No. 330 Market Street, San Francisco, Cal.
Telephone Number, Davis 771.

ANNUAL SUBSCRIPTION:
United States, Mexico and Canada..... $3 00

TABLE OF CONTENTS.

ILLUSTRATIONS.—Gallows Frame, Cripple Creek, Colo.; Head Gear Oneida Mine, Amador Co., Cal.; Head Frame, Van Anda, Texada Island, B. C.; Head Frame, Marble Bay, B. C., 281. Latest Mining and Metallurgical Patents, 287.
EDITORIAL.—Types of Head Frames, 281. Benefits of Concentration; Stamp Mill Mortars; Miscellaneous, 282.
MINING SUMMARY.—289-290-291.
THE MARKETS.—The Local Markets; Mining Share Market; Sales in San Francisco Stock Board, 306.
MISCELLANEOUS.—Concentrates, 283. Characteristic Mines of the California Gold Belt; The Diamond Drill in Germany; Some Experiences of a Working Miner, 284. The Seven Devils Country; Mechanical Haulage by Compressed Air; Absorption of Gold and Cyanide; How Low-Grade Ores Pay, 285. Gold Extraction; Heat in Ore Mines, 286. Latest Mining and Metallurgical Patents, 287. The Concentration of Ores; Notes on Gold Precipitation by Zinc Dust; Notes on the Occurrence of Quicksilver in Canada, 288. Industrial Notes; Personal; Commercial Paragraphs; Catalogues Received; List of U. S. Patents for Pacific Coast Inventors; Notices of Recent Patents; Recently Declared Mining Dividends, 292. Broken Hill Sulphides; Railroad Building by Music; Abuse of Machinery; A Natural Motive Force; A Substitute for Platinum; Krennerite. 293.

SOME Colorado mine managers have adopted the weekly payment of wages system, it is said, "with gratifying results," presumably to the workmen.

A SECOND oil exchange has been organized in San Francisco, Cal., as the result of the interest in the development of southern California oil lands.

A PREJUDICE appears to exist against veins in mica schist where the veins occur as lenses of quartz of varying size. Just why such prejudice exists is not easy of determination for the reason that, where such veins occur in a rugged mountain country, as good veins or lenses are found below the bottoms of the deepest canyons as are found on the summits of the highest hills, and therefore it is but reasonable to conclude that the lenses may be found to continue into the mountain to as low a level at least as the lenses appearing in the canyon bottoms; but for some reason the work in mines of this class usually stops with the first disappearance of pay ore, though the succession of lenses may be followed longitudinally for miles, their peculiar irregularities being recognized. Veins of this type undoubtedly extend to greater depth than is generally supposed, for, if they do not, then we must believe that the surface topography has a distinct relation to the distribution of veins, their continuity and depth, but facts tend to disprove this assumption.

THE jointing planes in rocks are often mistaken for planes of bedding, but where large exposures may be studied it will be observed that the joints are rarely really parallel though approximately so. They usually have the form of wedges though the bounding planes lie nearly parallel. Often the jointing planes are shown with great distinctness when in the same rock mass the bedding planes are almost wholly obliterated. In large rock exposures, such as the faces of vertical cliffs, a study of the jointing system often throws light upon the character and relation of the planes occurring in zones, which by reason of being connected with deeper seated regions have become the vehicles for ore deposition. This deposition of mineral from solutions rising along these passages from great depth take place in those portions of the fissured zones best prepared for their reception, notably in those portions of the zones where the greatest amount of crushing and pulverization has taken place. The zone may be narrow, less than a foot wide, or it may be hundreds of feet wide. In such wide zones the mineralization is usually found to occur in separate bands or streaks independent of each other, but having a general parallelism. Smooth, well defined walls are often misleading and crosscutting shows often that there are walls within walls in deposits of this character.

Benefits of Concentration.

One of the most important branches in the metallurgical field of the mining industry is that of concentration. In many districts too little attention is paid to it. Ores are shipped in bulk or are rudely hand-sorted and the best portion shipped to the smelters at a profit, it is true, but at a greater cost than would be necessary if concentration by mechanical means were first employed. The second grade ores remain on the dump in many cases, practically waste, though containing good values. In some mines the ores are so disseminated through the gangue that hand sorting can be carried on rapidly and economically, but this is only the case where the ore occurs in considerable masses. Hand sorting is not economically practicable when the mineral occurs in the form of disseminated grains.

Concentrating machinery is designed for specific purposes, but has considerable range of application. Most ores are easily concentrated at low cost, but some complex ores, such as those containing an intimate mixture of pyrite, galena and blende, afford unsatisfactory results. Fortunately, the latter class of ores do not occur universally, though found in large quantity in some mining regions. Generally, a plant consisting of rock breakers, rolls, trommels, jigs and concentrating tables, buddles or belt machines are better adapted to concentrating ores than stamps and concentrating machines alone, for the reason that a large percentage of the mineral is obtained in the first parts of the operation, the particles being comparatively coarse, the fine material being collected in the latter part of the process. Stamps crush all portions so fine that the subsequent recovery of the smallest particles, which in some ores crushed by stamps form the largest portion of the valuable mineral, becomes a matter of great difficulty. Rolls create a more uniform product, as they have a tendency to crack and not to grind the ore; and as most sulphide minerals break along the lines of their natural cleavage when subjected to crushing force, the small grains have angular faces which seem to facilitate their separation from the gangue. It is the aim of the successful concentrator to make as few slimes as possible.

When ores high grade enough to ship without sorting are concentrated by machinery, the gangue, if containing values in gold and silver, may be separately treated subsequently by amalgamation or some leaching process. If they will not pay for this subsequent manipulation they certainly will not pay the transportation and reduction charges when shipped to the smelter. It is a mistake which many miners make to send poor ore with rich, even though the average be high, for if the poor ore alone will not pay, it pays no better when mingled with the high-grade ore. This is a simple proposition which seems to be lost sight of in the desire to secure quantity. In shipping ores the aim should be to get as high value as possible in as small bulk as possible.

AN Eastern financial newspaper, speaking of the probable value of the stock of a certain mining corporation, concludes with this remarkable statement: "Still no one should forget that it is a gold mine, and that gold mines should be looked at, not annually, but very semi-occasionally, as they have a habit, so far as Boston investments are concerned, of coming and going almost in a night." If it is a fact that Boston investors have found that stock in gold mines has proven unsatisfactory as an investment, the fault must have been largely with the investors themselves. The gold mines of the United States have paid to their stockholders hundreds of millions of dollars in dividends and the stock of the leading gold mines constitutes as secure an investment as stocks of any other branch of industry.

AN unsettled condition of the political situation in Africa is attracting attention to that county. Statistics recently prepared by the Treasury Department of the United States shows that there has been a large increase in the demand for the manufactures and products of the United States, amounting since 1893 to an increase of 218%. Railroad bridges in the valley of the Nile, mining machinery for the gold and diamond districts and clothing and foodstuffs for the Soudan have all found an increasing demand.

Stamp Mill Mortars.

The form of the stamp-mill mortar has not changed materially since it was first introduced, in the early '50's, and it is not apparent that its general form should be changed. It is true the low, broad mortar, called by mill men in the early days "the hog trough," has been generally replaced by the high, narrow mortar with what has proven to be satisfactory results in most cases. This latter type of mortar increases the capacity of the battery, but it is much shorter-lived, owing to the increased scouring effect of the sharp grains of hard rock, which are repeatedly and constantly thrown against its sides and ends by the force of the falling stamp. This has led to the introduction of iron or steel plates, called "liners," which, when worn, may be renewed, thus increasing the life of the mortar by many years. Mortars, as now generally cast, are heavier than formerly, and it has been found an advantage to make them so, but the necessity for making the upper portion—that portion above the tops of the screen frames and feed holes—as heavy as they are made, is not apparent. It would seem preferable to reduce the thickness of the upper portion and to put the weight in the base. This is the portion subjected to the hardest service. The rapidly repeated heavy blows continue almost without cessation year in and out—in a single year about 260,000,000 blows are delivered by a 5-stamp battery—and this constant shock and vibration must be taken up and distributed by the mortar and absorbed by the mortar block. Realizing the necessity of rigidity, mill founders have increased the weight of the mortars throughout, and constructing engineers have attempted to make more and still more rigid mortar blocks. Recently concrete foundations have been introduced, and upon them a heavy anvil block is bolted, the mortar being bolted to this heavy casting. This must necessarily afford a block almost absolutely rigid. Some experiments in this direction have shown the desirability of heavy base; the base of the mortars may be made heavier with good results. For mountainous regions, where transportation is effected by the use of pack animals and men, the sectional mill has been designed. In these mills the upper portion of the mortar is made of boiler iron, riveted to the base, and mortars so constructed have given satisfaction, showing that a light upper portion is not detrimental.

IN the issue of Jan. 23d, '97, this paper published the names and addresses of 213 *new* subscribers received at the business office in the twenty-one days from Dec. 5th, '96 to Dec. 26th, '96, as the best kind of evidence of the growth of this paper's circulation. In the issue of October 2, '97, was stated the fact that during the twenty-six working days of the preceding month, September '97, there had been received the names of 179 *new* subscribers. This last statement was questioned, whereupon in the issue of October 9th, '97, were published the names and addresses of the 179 *new* subscribers to this paper received at the business office during the time specified. With these names and addresses was published an invitation to any one who doubted the statement made to write to any of those whose names were so published and ask if the statement made was true, so far as he was concerned. The matter is here referred to because of some similar doubt having recently been expressed regarding recent similar statement showing the steady growth of this paper's circulation in the mining world. On two occasions, as cited, were published the names and addresses of *new* subscribers received during short definite periods, as incontestable proof of what had been previously asserted. It was afterwards learned that on each occasion those whose names were so published were the subsequent recipients of certain "journals", who had so secured a desirable list of live men to whom their publications could be gratuitously sent in the hope of thus inflating a bogus "circulation." As such publication resulted in annoyance to those of our patrons, by the receipt of publications that they did not want, the action was not repeated and will not be. It was a case of assertion, and positive proof of the exact truth of the assertion, and as such was a success.

Concentrates.

THE duty on iron ore imported into the U. S. is 40 cents per ton.

NEVER pour water into acid to dilute it, pour the acid into the water.

THE market price of tin has more than doubled within the past year.

UTAH is the only American State that has in force an eight-hour law applying to miners.

'49, California; '59, Pike's Peak; '69, White Pine; '79, Leadville; '89, Cripple Creek; '99, —— ?

THE lines of the Snoqualmie, Wash., Power Co. contain 130,000 pounds aluminum wire, ¼ inch diameter.

DAMOURITE is a variety of mica, similar to the common, light-colored muscovite but containing more water.

TIN occurs in several of the United States, but is nowhere being produced in commercial quantity in this country.

THERE is as yet no coal discovery in the Klondike, though it would be a bonanza find, as coal in the Yukon is worth $50 per ton.

NOTHING is copyrighted in this journal, and any one, publisher or otherwise, using matter therefrom is merely requested to give credit.

THE eighth annual convention of the California State Miners' Association will be held in San Francisco on the 23rd, 24th and 25th prox.

THE chemical symbol HCN, or HCy signifies hydrocyanic acid or hydric cyanide (prussic acid). KCN, or KCy is the symbol used to denote potassium cyanide.

A SCIENTIFIC description of the copper deposits of the Seven Devils district, Idaho, written for this paper by Waldemar Lindgren, appeared in the issue of Feb. 4th, '99.

UTAH ore producers complain that local smelters, with one exception, allow but $2 a unit for their copper, when under the ruling price of the metal they are entitled to $2.50 a unit.

A HUNDRED pounds of ore does not furnish a reliable mill test in a mill doing custom work. Should a low grade ore follow a rich run, the result may be imagined. A ton is not too much.

A RUSSIAN OFFICIAL has figured out a time table which shows that, when the Transsiberian Railroad is completed, it will be possible to make a journey around the world in thirty-three days.

THE New England Exploration Co., organized in Boston, Mass., with a $5,000,000 capital stock, is credited with intention to "buy dividend paying mines," and employ "only expert commissioners."

WHATEVER the market price for copper, the U. S. Mint must pay it, as the Federal statutes prescribe 95% copper for the cents and 75% copper for the nickels, without reference to the ruling value of the metal.

THE wear on a narrow mortar of a stamp mill is greater than on a wide one. The wear on screens is also greater in narrow ones. The latter discharge pulp faster through a given sized screen than the former.

SO FAR as known the deepest diamond drill hole in the United States is the one at Lincoln, Neb., being bored under direction of the State Geological Survey. It is now 2463 feet deep, and the intent is to bore 1000 feet farther.

MILLMEN should always look closely to the adjustment of tappets in rapid-drop mills, for the wearing of shoe and die increases the height of drop, and a stamp set to clear the tappet when the shoe and die are new may strike when worn down.

MANY millions of dollars have been taken from the pocket mines of California by the use of hand mortars or spring pole and mortar. A single mine, the Bonanza, at Sonora, produced $1,500,000 with hand mortars, and over $500,000 in a 2-stamp mill.

IN the construction of a quartz mill it is desirable wherever possible to have the rock breaker set on a separate platform or on timbers in such a manner as to be wholly disconnected from the mill frame, thus avoiding the constant vibration caused by breakers.

FOLLOWING the recent reduction in government gold refining charges, it is semi-officially announced from Washington that the bureau of the mint will shortly order a reduction to be made in the charges for refining silver at the government mints and assay offices.

A SUPERINTENDENT in charge of the mining property of a corporation may contract a debt by permission of the board of directors, but the superintendent can not secure the debt by giving a mortgage on the property, even though he be personally the largest stockholder.

ACCORDING to the regulations governing the Paris Exposition, each nation contributing exhibits must come as a nation, and no States or sections are recognized. Labels may show from what part of a country exhibits come, but no special space will be allotted to any State.

IN old style mortars no provision was made for the constant abrasion caused by ore dropping from the feeders onto the lip of the feed opening, and mortars wore through in a comparatively short time. A thick lip is now cast on the mortar, or a steel plate is provided which may be renewed when worn.

THE next miners' rock drilling contest will be at the Festival of Mountain and Plain, Denver, Colorado, which will be held during the week beginning Sept. 25th, at which liberal prizes will be offered and in which a large number of expert drillers are expected to compete. Entries must be made by Sept. 20th.

IT is a good plan to cut the key seat of a cam shaft its full length, excepting that portion resting in the boxes. In a 10-cam shaft that portion resting in the center box should be provided with a nicely fitted steel bar, held in place by counter-sunk screws. All the keys should be fitted with care, avoiding the use of thin metal strips to fix defective keys. A good smith can forge a key to within a small fraction of the desired size, and the machinist can then file it to fit exactly.

ABOUT as big a price for a "prospect" as any told of is that of $125,000 for the "Carr strike," near Custer, South Dakota, recently. The purchaser was, however, unable to meet the deferred payments, and the sale fell through. The property is now reported sold again to the usual "Chicago syndicate."

NIOBIUM and columbite are minerals of a group of the niobates and tantalites and are chiefly salts of metamobic and metatantalic acid. Titanium is prominent in a number of the species. Niobium and columbium are essentially the same thing and are worth $2500 per pound avoirdupois, and titanium $1100 per pound.

"CONCENTRATES" can not guarantee absolutely correct answers to every question sent in, nor any answer to abstruse engineering and electrical problems, or manifestly silly queries. The idea and intent is to supply plain, exact, practical answers to such questions as naturally come up in the daily working life of our readers.

WHERE a hole has been worn entirely through a mortar it may be repaired by forging a plate to fit the hollow about the hole and fitting a rubber gasket between the plate and the mortar. A clamp similar to that in use in closing a manhole in a boiler must be provided, and with this device the hole may be tightly closed.

CYANITE is an aluminous silicate occurring in long, thin-bladed crystals aggregated together or penetrating the gangue. The color is usually blue, though sometimes the crystals have a blue center and a white margin, occasionally green or gray or even black. It is also known as disthene. It should not be confused with cyanide.

Do not feed quicksilver to a battery faster than it is required, nor permit the plates to become too hard by lack of it. Where the value of the ore is variable either condition may occur within a short time. When the value of the ore changes but little throughout long periods, a given quantity may be fed at stated intervals with safety.

IN mining deeds, where the consideration is stock in a mining company, it has been held that revenue stamps shall be affixed to the document in proportion to the par face value of the stock transferred, and not in proportion to its real or market value. The law provides that $1 worth of stamps shall be affixed for each $1000 value in the consideration.

A COLUMN of water at 60° F., 1 inch square and 1 foot high, weighs .433 lbs. Consequently a column 50 feet high would weigh 21.65 lbs. The pressure per square inch in a 6-inch or 8-inch pipe would be nearly 21.65 lbs. But the total pressure would be as much greater in the 8-inch pipe as the area of an 8-inch circle is greater than the area of a 6-inch circle.

THE Melones mine in Calaveras county, Cal., became famous in the early history of mining in California by reason of its production of rich telluride ores and native gold. The name is of Spanish origin, due to the fact that a Mexican there raised watermelons, which he sold at large prices. It was called the Melon Patch and finally Melones—Spanish for melons.

A SINGLE atom of an element may be substituted for one or more of another. This is termed their atomicity or atom fixing power. An element with an atomic fixing power equal to that of an atom of hydrogen is termed a monad; one with twice that power a dyad, with three times that power a triad, with four times a tetrad, and with five times the power a pentad.

THE pressure that tends to keep a check valve shut is equal to the area of its top surface, multiplied by the pressure per square inch in the boiler, and, in order to open the valve and force water through, the pump must produce a pressure per square inch on the under side of the valve which, when multiplied by the area of the under side, will overcome the pressure on the top.

THE variation of the magnetic needle changes constantly, though at an extremely slow rate. It also varies with each change of meridian. The daily variation sometimes amounts to ¼ of a degree, and always to several minutes. It is always changing from one side to the other of the normal variation. The line of variation moves westward at the rate of 3 or 4 minutes annually.

WHEN an ore is supposed to contain lead in an oxidized form, as carbonate oxide or sulphate, its presence may be detected by putting into a test tube a small quantity of the pulverized mineral and adding acetic acid, which dissolves the lead ore. To the solution add a few drops of a solution of potassium iodide when a yellow precipitate of iodide of lead will at once appear if lead be present.

SCARCITY of iron, increased demand for up-to-date mining machinery and the obsolete character of some appliances once considered effective and economical, have occasioned the recent purchase in various parts of Nevada of old mining machinery by San Francisco manufacturers for foundry use in supplying present demands. Virginia City and Eureka have thus been sources of considerable supply.

ONE of the principal causes of the failure to successfully amalgamate the gold in the ores of the Meadow Lake, Placer Co., district of California in the early days was the occurrence of the sulphide of molybdenum. This mineral has found a commercial value within the past two years and is worth $50 to $200 per ton, but is fatal to amalgamation when associated with gold ores. A process of careful concentration might solve the metallurgical problem at Meadow Lake.

CHLORITE is a magnesian silicate and is usually the result of the alteration of pyroxene, hornblende and other iron-bearing minerals, and forms a prominent constituent of the greenstone schists and slates. Rocks of this class characterize extensive rock formations, which are often the carriers of metalliferous veins. Chloride is the name generally given to the chloride of silver, though chlorine combines with a large number of other elements, the most common being its combination with sodium, forming the salt of commerce.

IN California the cost of sinking shafts of two-compartments in the soft crevices is about $20 per foot. A three-compartment vertical shaft in hard slate cost $45 per foot. The cost of a three-compartment shaft in hard greenstone (diabase) averaged $70 per foot for 1000 feet. The average cost of two-compartment shafts in granite in California is $40 per foot. This figure varies somewhat with the amount of water encountered. Some of the harder portions cost $100 per foot and other portions not more than $15.

MICA occurs in veins of coarse granite. Often all the ingredients are coarsely crystallized. These minerals are orthoclase and albite (feldspars) quartz, and mica. Accessory minerals are often black tourmaline, green apatite, black rutile needles often penetrating the mica sheets, and various iron minerals, such as wolframite, columbite, tantalite, etc. The formation should be fairly hard, to produce good mica. The best sheets do not occur close to the surface, as they have been decayed by exposure to atmospheric agencies. It would be desirable, to have solid undisturbed formation, to get the best material. Six feet is a very shallow depth at which to find good mica.

GOLD pockets occur under many conditions—in black slate, in talc, in diabase, at contacts, in limestone and in diorite, but usually where two or more veins or seams converge. There are usually three separate fissures, crevices or veins. First is the vein of quartz proper. This is usually barren except where the pockets occur. Next is the crossing—a seam or small vein or crack—cutting across the vein, and third the gold seam, the latter being important. It strikes nearly parallel with the vein and dips toward it. Where these three unite the pocket of gold may or may not be found. The occurrence of pockets is very uncertain under any circumstances; and, although the searching for pockets has been reduced to almost a science, the element of luck is an important factor.

A DANIELL CELL is a zinc plate immersed in dilute sulphuric acid contained in a porous vessel, outside of which is a perforated copper plate surrounded by a solution of copper sulphate. The reaction between the zinc and sulphuric acid produces zinc sulphate and sulphuretted hydrogen. The latter, however, unites with the copper sulphate. The former goes to keep up the supply of acid in the inner vessel, and the latter is deposited on the copper plate. The consumption of copper sulphate is kept up by a supply of crystals in a receptacle on top. A gravity cell is a modification of the Daniell cell, in which the porous vessel is not used. The two liquids are separated by their specific gravities: the copper sulphate surrounds the copper plate at the bottom, and the zinc sulphate surrounds the zinc plate at the top.

IN '98 there were forty-five dividend paying gold mining companies in the Transvaal, South Africa; the dividends aggregated £5,089,785. The number of non-producing gold mines in that district last year was forty. The mines' total expense was £10,961,812; the output was £16,240,630. Of this amount the Rand contributed 93.20%. The relative expense was as follows: Salaries and wages to whites, 33.82%; food and wages to natives, 26.25%; explosives, 11.85%; fuel, 8.2%; building material, 3.81%; iron, tools, shoes and dies, lubricating, belting, etc., 4.31%; chemicals, 3.25%; lighting, 1.29%; animal food, 0.32%; sundries, 6.9%; total, 100%. The average yield per ton of ore milled was 27.14 shillings. There were 9,034,792 tons extracted; the mills crushed 7,861,089 tons ore. The mills per stamp, per diem, crushed 4.561 tons (twenty-four hours). Stamps weighing 1250 pounds are now in general use.

AMONG the more manifest advantages of gas and gasoline engines are to be noted: Direct utilization of heat energy to drive the piston in a single apparatus; an economy of combustible per H. P. per hour, as heat is not wasted in a furnace or chimney, or doing work upon a heat medium which is not utilized in the engine; no fuel consumed to start motor, or after engine stops; engine ready to start on the instant, without any delay; by direct use of gas or oil in engines advantages of storage energy are reaped; advantage of subdividing power units in a large plant, each of which may receive its supply of motor energy through pipes without loss, and which can be run independently of each other as to time, speed or capacity, so long as the store of gas or oil holds out; storage of energy in the form of gas under pressure enabling great power to be stored in small bulk and with small weight, to be expended in motors as required.

BATTERY plates should be built separate from the mortars. There are various devices for accomplishing this. In some instances the plate frame is permanently fixed at a distance of 30 inches from the mortar, the pulp being carried from a box in front of the mortar to the plate by iron pipes. In some mills the plates are arranged in a series of drops, the upper plate being movable and running back on travellers, over the next section below. Either method removes the plate from contact with the mortar and block, and makes the interior of the mortar more easily accessible, as the workman may stand erect, working to greater advantage than where obliged to kneel on the board placed across the plate. The floor upon which the plate frames rest should not come in contact with the mortar blocks if there is any vibration. In fact, every precaution should be taken to relieve the plates of vibration, as it causes the amalgam and quicksilver to travel downward too rapidly.

AS BETWEEN "smokestacks" and artificial draught, the following are among the advantages afforded by the latter: Rapidity of combustion in the firebox not limited by atmospheric conditions. With a demand for high steam pressure and great capacity in a limited space the forced draught is a necessity, as in warship practice. With artificial or forced draught it is possible to increase the evaporative capacity of a given plant without other change than the velocity of the draught machine. This increase may be either permanent or to meet sudden demands for steam. With natural draught, the chimney must be designed to meet the maximum requirement, and will be partly shut off at other times. It is also possible to burn inferior, cheaper and smaller sizes of fuel with artificial draught, because a high pressure can be maintained which will force the necessary air through a compact body of fuel. Then, too, draught arrangements are more portable than chimneys can be. The plant is more flexible for changes in quality or size of fuel, and the desirable thickness of fuel bed on the grates. Grate bars can be altered more easily, if this should be desirable. Where high stacks are not made necessary, the cost which they entail is avoided or is obviated by a less cost of the draught machine. The troublesome settling of massive stacks is avoided when foundations are difficult or defective. Leakage of air into the setting does not occur with forced draught on the pressure system.

Characteristic Mines of the California Gold Belt.

NUMBER XI.

Written for the MINING AND SCIENTIFIC PRESS.

For many years the Utica–Stickle mine at Angels has occupied the position of the most important mine in Calaveras county. In its early history this property attracted no particular attention and was not considered particularly meritorious. It had several successive owners, each of whom did considerable in the way of development, but until it came into the hands of the present owners was not a paying proposition. With the greater depth and extension of its workings it became evident that the great ore shoot which has made the mine famous did not come to the surface within the limits of the claim, but north of it. Two claims north of the Utica mine quartz croppings were discovered and the vein worked in early days, some coarse gold being obtained, but for some reason the shoot was not followed on its downward trend southerly along the vein to any considerable depth, probably because it split up and was lost.

The Utica–Stickle mine is generally spoken of as lying in the hanging wall of the mother lode, the Madison–Gold Cliff vein being considered the main lode or vein in this portion of the belt. As explained in a former paper on this subject, the central lode of the gold belt is about three miles in width in the vicinity of Angels, and there are numerous large, prominent croppings at various parts of the belt, both east and west of the zone in which the Utica mine occurs. No prominent outcrop marks this vein on the surface, and although quartz occurs abundantly in the lower portion of the mine the fissured zone along the surface is represented by a much-decayed iron-stained amphibolite schist, any portion of which contains gold, some of it in paying quantity.

This broad zone of amphibolite schist, however, contains an object lesson of importance to prospectors searching for deposits of similar type. Throughout the gold belt the amphibolite schist is almost universally, if not wholly, the result of the alteration of diabase and diorite from their normal granular condition to a metamorphic schist, by compression, shearing and the subsequent change of the original minerals to other substances, the most notable being the change of augite to uralite, and by further alteration to chlorite, and the similar alteration of hornblende to chlorite. In some cases the alteration has resulted in producing vein-like sheets of talc schist. These rocks generally retain their characteristic green color, ranging from light to dark green of various shades. At the Utica mine, however, for a distance of nearly 2000 feet the amphibolite schists are porous and stained with the brown oxides of iron due largely to the alteration of the auriferous pyrite which was originally disseminated throughout the schistose mass.

These rocks strike a few degrees west of north and dip easterly at about 80° at the surface, but considerably more than that in depth. The vein, or, more properly, zone, is not well defined, but consists of a broad mass of amphibolite schist (chlorite and talcose schist), throughout which occur many lens-shaped sheets and irregular bodies of quartz, large and small. Much of the schist is very silicious. A portion of the diabase is splintery, the shearing process having not progressed sufficiently to make it a typical schist. The lenses and masses of quartz, the chlorite and talcose rocks all contain gold, and the extent to which these rock masses are gold-bearing usually determines the limit of the ore shoot. The greater portion of the rock within the recognized walls contains sufficient gold to constitute pay ore. Between the masses of quartz and gold-bearing schist there are, however, considerable masses of rock practically barren of gold, from an economic standpoint. In some parts of the lode are seen reticulated seams of quartz, penetrating schistose rocks of considerable extent. This is one of the prominent features of the lode.

Perfect series of transition rocks, from normal granular diabase to typical chlorite and talcose schists, may be found in many parts of the mine.

A very important geological feature in this mine is the occurrence of what has the appearance of being an intrusion of eruptive rock, which has been thrust into the great masses of quartz and amphibolite schist. This rock always accompanies the large pay shoots, and where the best ore occurs there will this intrusive rock be found also. It has a peculiar light grayish brown—almost straw—color, and once observed may readily be determined wherever seen again. It constitutes masses of varying size; some of them are narrow, dyke-like bands, and in other portions of the mine it may be seen in masses 50 feet or more in width. This rock differs so materially from either the massive quartz or the normal diabase or the schistose rocks that it may be readily distinguished. It is always fine, granular and appears to be more acid than the diabase. In physical appearance it greatly resembles granulite (a type of granite). This intrusive rock is much silicified and is abundantly impregnated with auriferous iron pyrite and constitutes, in fact, one of the most important sources of ore in the mine. It usually contains an intricate network of quartz veinlets, besides the large amount of quartz which has infiltrated into the mass. In this rock calcite is also abundant. The ore shoots range from 8 or 10 feet to more than 100 feet in width. The occurrence of the dyke rock described above has also been observed by the writer in mines near Sutter Creek, in Amador county, Cal., and in this latter instance it was also gold-bearing and presented essentially the same physical and mineralogical conditions as those distinguishing it at the Utica mine. As this rock has an apparent beneficial effect on the occurrence of pay ore, it would seem to be a good indication to follow in exploring unknown ground. At one point in the Stickle mine, 1200 feet from the surface, the dyke rock was found as a small vein, about 4 inches wide, contorted like the letter S, and cutting through and across the amphibolite schists, clearly indicating its later origin. At this place there was very little quartz present and not much iron sulphide, and—a more important fact—very little gold, but following this small intrusion upward it led to large and rich ore bodies, and it is not unreasonable to presume that, followed in its downward course, it might lead to other large and valuable deposits below.

The width of the Utica–Stickle ore zone, the complete alteration of the normal rocks, and the abundant evidence of extensive dynamic action, all lead to the conclusion that the forces which produced these effects were deep-seated, and if there were any doubt about it the occurrence of the intrusive ramifying dykes would tend to confirm the belief in the deep-seated origin of these forces. The mineralizing solutions coming from below found easy passage along this broad avenue of crushed foliated rock, and along this same line of weakness the dyke rock forced itself. Whether or not the schists and quartz masses were gold-bearing prior to the injection of the dyke rock there is no way of knowing, nor is it important to know, but as gold occurs elsewhere in the neighboring mines in amphibolite schist, and in the accompanying quartz, where this dyke rock is not found, it may be presumed that the schists were already gold-bearing, but that the mineralization continued after the intrusion of the dykes there can be no question, for it is found silicified, impregnated with pyrite and gold-bearing to a notable extent.

The ores of this mine are free milling to a great extent, though an exhaustive system of concentration of auriferous sulphides is practised, by means of vanners and canvas slime tables. The sulphides are treated by the Plattner chlorination process.

The occurrence of the intrusive rock in the Utica–Stickle mine and its apparent beneficial effect is not an analogy. The great Homestake mine in South Dakota is in some respects structurally similar. There the country rock is hydro-mica and sericite schist, very silicious and inclosing immense masses and vein-like sheets of quartz, very similar to the occurrence at the Utica–Stickle mine.

This formation in the Homestake mine proper varies from 200 feet to 450 feet, and in some of the adjoining mines is much larger. The most striking feature in the similarity of these mines is the occurrence of a ramifying dyke rock in the Homestake. This intrusive is felsite of fine texture and light, ashy gray color, almost white, and containing an abundance of pyrite in microscopic crystals. The felsite is not notably gold-bearing, but it seems to have had a beneficial effect on the ore bodies. The schist and quartz were gold-bearing prior to the injection of the felsite, as evidenced by the occurrence of gold-bearing conglomerate above the vein, which lies unconformably upon the upturned schists, which are of Archæan age. This conglomerate forms the base of the Cambrian series in the Black Hills, and, while containing abundant gold at and near the Homestake mine, contains no pebbles of the intrusive felsite, showing that the intrusion was later. Farther to the northward the Father de Smet mine, on the same zone, contains no intrusive dyke rock, though otherwise similar. This mine paid for a few years and was abandoned, being no longer productive. The Highland mine, lying between the De Smet and Homestake, pays largely and has the dyke rock as well.

Dykes as an accompaniment of veins and ore deposits are a well-known feature to the miner, and they occur in a great variety of form, but the similarity of the occurrence in the Homestake and Utica–Stickles mines is noticeable. Northwest from Angels the gold belt continues, but is not clearly defined. The belt narrows toward San Andreas, where it is less than a mile in width. A number of mines have been opened between Angels and San Andreas, but none of these have as yet developed into large producers.

W. H. S.

KARL KOBRICH, who died at Bozen, in the Tyrol, in May, introduced the diamond drill into Germany, and devised many improvements in boring and underground explorations with the drills. It was said that he had charge of over 500 borings and that the total length of the bore holes put down under his direction was 150,000 metres. It was at his instance and under his supervision that the deep drill hole at Parnschowitz, in Upper Silesia, was made. This is the deepest boring ever made into the earth's surface, the drill having gone down 6500 feet.

Some Experiences of a Working Miner.

NUMBER XXXI.

Written for the MINING AND SCIENTIFIC PRESS.

The P—— Mining Co. had a good prospect, and it led to the sinking of a shaft in what the miners called "pot granite." I have never been able to trace this peculiar name back to its origin; but by experience with granite of this description I have learned that it is a granitic rock in which the feldspars have suffered considerable decomposition through meteoric agencies, and, consequently, is comparatively soft; but in depth it is found sufficiently hard for all practical purposes, requiring skillfully tempered steel to stand. The shaft was sunk several hundred feet and unexpectedly came upon a change in formation—serpentine it was called. The shaft continued and soon entered quartz rich in gold. The shaft continued through the ore shoot, serpentine was found below and sinking discontinued. The ore shoot proved rich and a great deal of gold was taken from it.

The occurrence of this shoot of ore led to a peculiar theory—that the granite was a cap rock, and it was only necessary to sink through it, and below in the serpentine would be found rich shoots of ore similar to that in the P—— mine. I went to the P—— mine and investigated the proposition at the request of a capitalist who had spent a large amount of money sinking a shaft into the granite cap, but had not yet gotten through it and was becoming discouraged. I found the granite traversed by a large dyke of diorite, which in the P—— mine had been sheared and altered into chlorite schist (not serpentine), and within this dyke the quartz vein had formed which contained the gold. The dyke dipped at an angle of 50° below the plane of the horizon, and on its lower side the granite occurred again as above. The nearest slate rocks were nearly two miles away. I told the capitalist his chance of striking a change of formation was very poor indeed; but he was not satisfied and continued his shaft nearly 100 feet deeper. As might have been expected, it was still in the granite.

On the strength of the granite-cap theory, a noted miner got a company to put up a large sum of money, leading them to believe he would sink through the cap and find great veins below. He never got through the cap, either, but spent all the money.

Granite does not occur as a cap-rock, like some porphyries and other intrusive rocks—at least, I have never seen it in that position.

* * *

The bane of the new mining camp is the fellow who arrives in the early days of the rush, pitches his tent, or, more often, his blankets, having no tent, and then starts out to claim the county. With a hatchet in one hand and a leadpencil in the other, he blazes and claims as far as he can walk in a day, or if there be no timber, he builds monuments. He keeps this up for a week or so, and then comes into camp to stay. He always talks a lot, but does no work. He takes occasional trips out among the hills to see if anyone has made a discovery on any of his claims. Not infrequently his industry in this direction is rewarded by finding some one actually working on one of his mines, and a wordy difficulty at once ensues—the more apparent the value of the discovery, the more heated the discussion as to who is the rightful owner. This fellow will do nothing himself, and his intimidating methods prevent others, who would otherwise do something, from working, thus retarding the development of the entire camp. This state of affairs has led to some remarkable location notices being posted. I recall one in particular, whereon the locator defined, in unmistakable language, the boundaries and corners of his claim. Following this were instructions concerning unlocated ground in the vicinity and a request to whom it might concern not to attempt to locate on his ground, or in any manner disturb the stakes, under penalty of being shot. No one ever disturbed any of his stakes or interfered with his claim in any way.

* * *

P—— and O—— were good miners and also wide-awake prospectors, but they had no luck apparently. They worked for wages in various mines and each summer and fall they went prospecting, but could locate nothing of value. One day the news came of the rich strike at Salmon river, and they got together enough money to make the trip, and left D—— for Wood river. For months they toiled in the rugged hills of Idaho. Others found rich ore, but they found nothing. Finally, having spent all they had, they sent back to D—— to friends and begged for enough money to return to the old stamping ground. They went back, arriving penniless and in debt. Most men would have been discouraged by such ill luck, but P—— and O—— were good stayers. They had been at home about a week when on Sunday they took a walk, one of them carrying a little prospecting pick. They went out of town about four miles, having no particular objective point, not prospecting, but merely strolling about on a beautiful day. Noticing a little vein of quartz a few feet up on the side hill, P—— went up to it

and knocked off a piece. It was sprinkled with coarse gold. Here was a strike at last. They dug into it a little with the pick, and broke out about $50 worth of rock—only a few pieces—and then returned to town, secured picks and shovels, axes and other necessary tools, and before night had located the mine. They took thousands of dollars from their strike in a few weeks and sold out for a goodly sum. Their experience simply illustrates the necessity of perseverance. Luck is surely an important element in mining, but to find a rich mine it is necessary to search for it.

* * *

There are a number of ways to equip a mine, and the way some of them are equipped affords an excellent example of how it should not be done. The O—— B—— mine is one of this class. Its mill was built piece by piece at various times. The interior arrangement is not good and the outside is worse. The waste dump is encroaching upon the mill and is likely to crush it; the tailings have to be handled two or three times to get them into the leaching tanks; the sulphurets have to be carried up hill. In fact, everything seems to work the wrong way, and yet the topography of the country affords every opportunity to have arranged an ideal plant, where the ore once dropped on the grizzly at the top of the mill would pass from one operation to another by gravity, requiring no handling and reducing the cost of handling materially. Even if it were so little as 25 cents per ton, it would make a difference of thousands of dollars to this company every year.

The Seven Devils Country.

The Seven Devils range of mountains in Idaho is thirty or forty miles in length and fifteen to twenty miles in width. The Weiser and Salmon river valleys border the range on the east. There are seven distinct peaks in the range, none of which have an altitude of over 9000 feet, but this appears high as the adjacent streams and valleys are but 1000 to 2000 feet above sea level. The growth of timber does not reach to as great an altitude as in Colorado and the peaks stand out clear and rugged, while the lower slopes and foothills are most densely covered with fir, pine and spruce trees. On the west or Snake river side the confines of the range are sharp, generally terminating with the great canyon, which is almost as impressive as the Grand canyon of the Arkansas in Colorado, and more so than the canyon of the Gunnison. Lateral canyons and gulches reach out into the mountains, and where they debouch into the main canyon they have formed frequent extensive beds or bars of sand and gravel that have yielded much placer gold in the past. Some of the washings are so inaccessible that early miners were let down from overhanging precipices and left there for the summer to wash for gold and drawn out again at the close of the season by their friends who meanwhile were otherwise engaged.

Monument mountain, on which the copper deposits or veins are situated, has an altitude of probably 8000 feet and is five miles in length from north to south and three miles in width. The territory over which the copper extends is equal to six square miles and is four miles distant from the Snake river.

The crown and the northern side of the mountain are composed of a gray eruptive granite, considerably decomposed in places. Here and there are found remnants of limestone. Three-fourths of the west and south slopes of the mountains is covered with porphyry, and the foothills sloping away to Snake river are composed of the same material. Between the porphyry and granite is a stratum of varying thickness, in places disappearing entirely. It is next to the limestone or replacing it entirely that the Seven Devils copper vein is located. On the northern end at the Peacock mine the vein crops at an altitude of 6700 feet. The ores are called peacock ores from being of a peacock blue color. They also carry silver and gold in combination with copper. In the Peacock mine a large body of ore has been uncovered by the action of the water in a small stream directed upon it. The lowest estimate of the ore uncovered is 75,000 tons.

The principal group of mines is the Peacock, consisting of the old Peacock mine, the Confidence, Bodie, Standard, South Peacock and Copper Key.

Associated with the ore are great quantities of garnets, also iron, quartz, talc, spar, amphibole and chrysolite.

The Peacock mine occupies the northern terminus of the vein. Its outcrop or exposed ore mass covers about 150 feet of the apex of a ridge and down its northeasterly slope for 350 feet or a superficial area of 50,000 square feet. It is apparently a mass of copper ore in place. Some sluicing for free gold in the detritus had taken place. On the west side of the ore body eruptive rock is disclosed, on the east side granite, on the south a mass of garnets and on the north amphibole and chrysolite. A shaft 25 feet deep passes through a mass of decomposed limestone, oxide or iron, manganese and copper, and carbonate of copper. Going over the surface the indications and excavations made would warrant the conclusion that the ore averaged at least 15 feet in thickness over the 50,000 superficial feet of ore exposed. Of this amount probably one-sixth is bornite that returned an assay of 47 7/10% copper and 15 ounces of silver, and one-third is carbonate and silicate which, sampled, gave an average of 17 3/10% metallic copper.—Salubria Citizen.

Mechanical Haulage by Compressed Air.*

By E. P. LORD.

Mining has been one of the most active means of giving prominence to compressed air. In these days of active competition and imperative demand for decreased cost of production, great economies and improved appliances for cheapening the mining of coal have been absolutely essential to profitable mining. New fields, as soon as developed, have felt at once the necessity of installing the most approved machinery for mining, pumping and haulage; in fact, these improvements have been imperative to keep in business. The mule, which has so long been used for haulage, has been very generally supplanted by more powerful agents—steam, electricity and compressed air. It is to the latter power as applied to the motor for haulage purposes that I intend to principally confine my remarks.

In much work—in mine tunnels, confined spaces, etc.—compressed air has fully demonstrated its usefulness. The work accomplished with it in the Jeddo tunnel at Hazelton needs no reference to it here. Early uses of compressed air hardly presaged the wonderful development and application of this power to-day. For mine haulage it is largely supplanting the steam locomotive, with its attendant disadvantages, and now electricity is about its only competitor. Until this competition manifested itself, air was generally considered a very undesirable power at best, and in many installations, more particularly haulage, it was not thought of. I do not wish to be construed as saying that electricity and compressed air do not very frequently work in mutual harmony. Each has its own field of work, for which it is singularly fitted, and where no question of competition can arise.

Electricity can be used in most cases successfully for haulage. It can also be used for pumping, and made a success as far as operation is concerned, but in many cases at an excess of cost over compressed air. But when you come to cut coal with electricity many operators claim that no such results can be obtained as with compressed air, to say nothing about the increased cost of installation and subsequent operation. I have found it extremely difficult to get any statements from those using electricity for coal cutting, and there is no doubt or question but that there are some veins of coal which cannot be cut with the type of machine which is driven with electricity that could be successfully cut with what is called the punching or pick machine. Where compressed air is superior for transmitting power for coal cutting and pumping, is it not reasonable to conclude that a good deal of consideration should be given to it for haulage?

Some engineers believe that the electric motor is not an economical machine where the use of power is to be variable and intermittent, it being essentially a constant speed machine. If we so block an electric motor that it cannot move, a considerable current of electricity will run through, without doing any work; while a compressed air engine wastes no air or energy in starting, for air only escapes with piston movement.

The average mine engineer will usually show the liveliest interest when approached on the subject of an air haulage plant; but when he is called upon to choose between air and electricity, no doubt he feels that the best known and understood agent is the best and safest in his case, although the compressed air plant, if successfully installed and started, might prove the most economical to his company.

The last few years have witnessed a remarkable development of compressors and compressed air apparatus, due, no doubt, quite largely to the active competition of electricity in the many fields where this power is used. The great improvement made in compressors, together with reduced cost, have led to their more extensive adoption and the enlargement of their uses. In all respects its progress has fully kept pace with that of electricity. The compressor people are now called upon to design and construct machines to develop heat and to develop cold; to move air with a force only sufficient to press gold into a sensitive tooth, and to blow the shot from a cannon. There is hardly a department of any large shop or manufactory that cannot testify to the remarkable economies that this power, ingeniously applied to various machines, has established. There are not less than two hundred distinct and established uses of compressed air, to 90% of which electricity is inapplicable; and in the remaining 10%, constituting the field open more or less to other agencies besides air and electricity, we find air generally has the advantage. Except within the last few years compressed air catalogues have been almost the only literature on this very important subject, while to-day we can hardly pick up an engineering paper without running across some article, paper, or special mention of the great benefits that this new power is establishing for its recognition in the mechanical world.

Compressed air has marked advantages over any other class of haulage, in that it is free to go wherever there is a track laid; the distance run with one charge of air is only limited by the capacity of the motor tanks. Great advancement has been made in the improvements of compressors, pipe lines, pipe connections, motors, methods of charging, etc.; so that for efficiency it is admitted that compressed air runs electricity very close for a long distance transmission. It is equally efficient and safe in fiery and non-fiery mines, and materially assists ventilation by the air given out by the exhaust. Too much stress must not be laid on this, for efficient ventilation must be provided for in any case; but compressed air is now used for driving mining machines in rooms or in butt entries, ahead of the general work and beyond the range of general ventilation. It not only supplies the necessary power but furnishes an ample supply of fresh air, thereby materially reducing the risk to life or property. In the butt entries and rooms where ventilation has been difficult, and where, on account of low roofs, light rail, etc., other classes of power have not been introduced, the compressed air locomotive has been installed with very manifest success.

* Condensed from a paper read before the Anthracite Coal Operators' Association.

Absorption of Gold and Cyanide.

The following experiments were conducted with the view of ascertaining the loss of gold and cyanide caused by absorption. The materials selected were those which commonly come in contact with cyanide solutions. The bulk of material as compared with the volume of solution used is probably larger than ever occurs in practice, but it serves to show that there is a noticeable loss of both gold and cyanide caused in this way:

No. 1, plain pine block ¾"x1½"x6", treated with 450 c.c. of solution.

No. 2, same as No. 1, except given a coat of asphalt.

No. 3, strip of 12-ounce burlap filter cloth 8"x24", treated with 350 c.c. of solution.

No. 4, iron (nine 10" nails), treated with 150 c.c. of solution.

Each of the above was placed in a glass-stoppered bottle and allowed to remain in a dark place for fourteen days; these precautions were taken so that no decomposition of the solution would occur by the action of the air or light. The original solution contains 1.20 ounces gold and 2.4 pounds cyanide per ton of solution.

No. 1 after treatment shows 1.015 ounces gold, 1.8 pounds cyanide, per ton of solution.

No. 2 after treatment shows 1.128 ounces gold, 2.1 pounds cyanide, per ton of solution.

No. 3 after treatment shows .776 ounces gold, .8 pound cyanide, per ton of solution.

No. 4 after treatment shows 1.20 ounces gold, 1.20 pounds cyanide, per ton of solution.

Thus it will be seen that there is a loss of .185 ounce gold and .6 pound cyanide per ton of solution in the case of ordinary pine, while a block the same size and under the same conditions, except being coated with asphalt, shows a loss of .072 ounce gold and .3 pound cyanide per ton of solution.

The largest loss is occasioned by the burlap filter cloth, which causes a loss of .424 ounce gold and 1.6 pounds cyanide per ton of solution. The iron causes no loss of gold and but .2 pound cyanide per ton of solution.

[While the losses indicated in the result of the above-described experiment are large, it is doubtful if, after having absorbed the quantity of gold and cyanide indicated, a much greater quantity would be taken up by longer contact. That is to say, the materials coming in contact with the solutions having become saturated, no further absorption would take place.—ED. M. & S. P.]

How Low-Grade Ores Pay.

In getting up a mining prospectus it is usual to publish assays as taken either from the surface or from different parts of the mine in process of development, and by these assays many are guided in making their investments. Assays that run from $100 up to several thousands per ton of ore are generally the most attractive, and, assuming them as correct, the investor buys the stock, either not knowing or forgetting that few mines ever did approach any such average.

Ores running from $8 to $10 per ton are more or less disregarded, and those showing from $3 to $5 are considered as of no account whatever. It is just here that the investor makes a serious mistake.

If an ore is a smelting one, such as the Le Roi or War Eagle, to make a profit it is necessary that it should show far higher values than a free-milling proposition; but few mines that we ever heard of yielded any great quantity of hundred-dollar ore, to say nothing of thousands. A free-milling ore averaging from $8 to $10 on the plates and in the con-

centrates will not only pay, but pay well, even though the veins be narrow and a large margin left for other possible disadvantages. The best paying mines are those that in Ontario are considered of no value, viz., the low-grade propositions showing from $3 to $4 per ton or less. Among mining engineers and mining men generally it is well known that, given a large body of ore, with suitable facilities for work-it—such as water, fuel, etc.—there is no better paying investment than an ore showing $3 per ton. Among the best paying mines in the world are the large mines in Alaska and South Dakota, and all are low grade.

It is a common error that these ores can be mined so cheaply and profitably because the mines are worked in the open, thus avoiding the necessity of shafts, tunnels, pumps, etc., but this is not the case. They are all operated with shafts, tunnels, etc., as are the higher grade mines in Ontario.

The real reason of their success is not the existence of unusual facilities, but because they are operated on a very large scale. Few of them would pay a profit, or even expenses, were they run with the 5, 10 and 20 stamp mills, which, with few exceptions, seems to be the limit of ambition in Canada. The Alaska-Treadwell operates 660 stamps, the Alaska-Mexican 240, the Alaska G. M. Co. 220, the Homestake and Highland of South Dakota 840 stamps. To all of these mines more stamps are to be added as development proceeds. As showing what can be accomplished with plants such as the above, we append the following table:

Mine.	Capital.	Par value per share.	Present quotations.	Total paid in dividends.	Paid first five months 1899.	Average value ore per ton.
Alaska-Mexican	$ 1,000,000	$ 5	$ 5 50	$ 353,031	$ 36,000	$2 31
Alaska-Treadwell.	5,000,000	25	35 00	4,070,000	150,000	1 63 to 2 50
Homestake	12,500,000	100	.....	7,556,250	437,500	3 00 to 4 00
Highland	10,000,000	100	.....	3,924,718	140,000	3 00 to 4 00

We have dealt with only four of the five mines quoted, as we could not get full returns for the Alaska United G. M. Co.; but as an instance of what it can do, with an ore averaging $3 96 per ton, the last published returns for a forty-three days' run shows a net profit, after paying all expenses, of $23,412.

For the month of June the Alaska-Treadwell mine, working with an ore that averaged only $1 63 per ton, crushed 66,098 tons and a net profit of $75,034 was shown.

The capitals of all these companies are large, and we do not know at what price per share they were put upon the market; but all of them still hold treasury stock, every share of which can be sold at a premium. The Alaska-Treadwell, Homestake and Highland have paid more in dividends than they originally cost, and, in addition, have not only an enormous development, with hundreds of thousands of tons blocked out, but the huge plants are paid for.

There are many of these low-grade ores in Ontario offering better inducements to the investor than those of either Alaska or South Dakota, and we trust, for the benefit of the country, that they will not in the future be so studiously disregarded.

As an additional advantage offered by low-grade ores, the veins have seldom been known to pinch out. Once found, they will last for generations.—Canadian Mining Gazette.

Gold Extraction.

The processes used upon the Witwatersrand gold fields for the extraction of the precious metal have approached nearly to perfection. But J. R. Williams, the newly elected president of the Chemical and Metallurgical Society, said in his inaugural address that there is still room for improvement. It appears from his statement that, on the average, there is still 10% of the gold contents of the ore lost after all the different and delicate processes which are used upon these fields. To reduce that percentage he considers should be the object of chemists and metallurgists in the future. Every pennyweight gained in this direction, or even a few grains per ton, would make a very material addition to profits and act as a stimulus to the further development of the wealth contained in the reefs. Only a few years ago gold ores which on the average would yield an ounce per ton were those only regarded as payable, but now mines which produce ore of half an ounce per ton are regarded as rich, and six and seven pennyweight mines pay a very respectable return upon the capital legitimately expended on their exploitation. In former days tailings and slimes were regarded as rubbish, to be got rid of by any possible means, but the case has now altered, and both these results of crushing are made to yield up a large percentage of the total amount of the gold output. That such a revolution in practice has been brought about by the combined efforts of the chemist, the engineer and the capitalist is unquestionable. And yet science is not satisfied so long as a single grain of gold remains which ought to be won from its matrix. It is, of course, conceivable that perfect extraction would cost more than the results were worth, but if Mr. Williams' estimate is correct, as it doubtless is, as to the quantity of gold recoverable, there is a fair margin for profitable operation in that direction. When regard is paid to the rapidly increasing list of new patents connected with all departments of the gold mining industry in this country for the disintegration of ores and their subsequent treatment by mechanicians and chemists here and in other parts of the world, it is fair to assume that some, at least, of the new or improved processes will be found not only to increase the average yield, but to ensure greater economy in the mode of treatment. It is very satisfactory to learn that the capitalists are fully open to the consideration of new processes, and, it may be assumed, are reasonably ready to give promising processes a fair trial, or to afford reasonable facilities for testing laboratory results upon a commercial scale. There can be no doubt that many a good idea has been lost to the world by want of co-operation between the man of money and the man of brains; but, most fortunately, that has not been the case upon the Transvaal gold fields. That it is so is proved by the readiness with which the large expense of erecting cyanide plants for the treatment of tailings and slimes has been incurred by the chiefs of the mining industry, and that, too, when cyaniding was not considered an essential part of the treatment of gold ore residues. The foresight and enterprise which have been so fully justified in the past are not likely to be lacking in the future. There is still 10% of gold remaining to be won from the ores, and no doubt both chemists and engineers will set their wits to work to gain as much as possible of that which is at present regarded as necessary loss. It is quite evident, also, from the president's address that there is still something to be learned by mine managers. The ores of one mine are not identical with those obtained from others, although they may be obtained from the same reef. Some classes of ore may yield satisfactorily with comparatively coarse crushing, while in others the finest possible pulverization is required to render the gold recoverable. That is a matter for special investigation by those who have charge of the mechanical department of mine work. Mr. Williams points out that careful sampling is very essential, and that when that is done merely by the rule of thumb the assay values are comparatively worthless. The point was forced home by a statement that in a case which came under his notice 102% had been recovered by the mill alone—the sands and slimes having been untreated. The necessity of accuracy with regard to the tonnage crushed was also enlarged upon, and there can be no doubt that there is a sad lack of uniformity of practice in that respect among mill managers. "Have you ever thought what 1% extra extraction means?" asked the president of the society, and then, answering, he pointed out that every additional 1% gained meant £200,000 per annum. To save that sum is an object worth working for, and as an aid thereto Mr. Williams counseled attention to the filling of the cyanide tanks, in order to get rid of the slimes; in the slimes tanks to beware of the sands. He also inculcated the necessity of giving more thought and time to the precipitation of gold, which, of course, means that all engaged in the various processes should trust more to intelligent observation than to mere precedent in regard to working. Cyaniding is a scientific process, and requires to be intelligently used in order to get the best results. Some classes of ore require different proportions of cyanide from others, and to be subjected to different times for the leaching, and it is the business of the cyanide manager to adapt his solutions and times to the class of tailings or slimes which he has to treat.

From Mr. Williams' remarks upon the diversity of conditions to be found in different mines it might be used as an argument in favor of less changing about from one mine to another of mine managers and their managerial staff. It is almost impossible that there should not be a loss to the companies, temporarily at least, resulting from changes of this description. A mine manager who knows that he is likely to be supplanted at short notice has scarcely an inducement to do his best for the mine when he has reason to think he will be superseded by another.—South African Mining Journal.

Heat in Ore Mines.

It has been given out that at a depth of 6500 feet the Calumet & Hecla mine is so hot that men can work only a few minutes at a time without becoming exhausted, the temperature being given at 100° above zero.

The deepest shaft in Calumet, and in the world, is the Red Jacket shaft of the Calumet & Hecla Mining Co. It is a vertical shaft 12½x25½ feet inside of timbers. It is located at the northern end of the mine and directly in front of No. 4 shaft, an inclined one which has followed the belt of copper-bearing conglomerate from surface downward. The vertical shaft encountered the Calumet conglomerate at a depth below surface of 3295 feet, this corresponding with the fifty-sixth level of the mine, and has been carried downward past that point to a total depth of 4900 feet, which will be the bottom of this opening, as from its lowest point the company can secure all the copper in this end of the property.

This big shaft is connected at several levels with the No. 4 inclined one. The fifty-sixth and fifty-seventh are holed, and the sixtieth, sixty-third and sixty-sixth are also connected, the sixty-sixth having been holed through a few days ago. The connections are being made at every third level with No. 4, the levels being 60 feet apart. At the bottom of the shaft the temperature is 85° above zero. The increase per 100 feet is very small, and to thoroughly determine this a careful test of the temperature of the rock has been under way for the past year or more.

Holes have been drilled in the wall rock, and in these slow-registering thermometers have been placed and the holes in the rock plugged up. In a month from the time of sealing the holes were opened and the temperature taken and recorded. This has been going on from the surface to the bottom of the shaft. It is the plan to make the test absolutely accurate, as it is intended for application to the future working of the property at greater depths than yet attained. It is desired to get correctly the heat of the different elevations as well as of the different rock strata. The company will probably issue a bulletin on its findings. As the levels are being connected with the workings of the mine by the crosscuts the circulation of air is growing steadily better, and while a temperature of a little over 80° above zero is a warm one, it can be withstood without having to observe the short shifts of mines located in other parts of the country. The Calumet & Hecla has twelve shafts upon its conglomerate, all of which are connected at many levels.

At No. 3 shaft of the Tamarack Mining Co., where all the shafts are vertical, the temperature at the bottom of the shaft is 82° above zero. This is 4500 feet below the surface. At this shaft the atmospherical condition is improving as they are connecting with the levels at No. 4 shaft. They now have connections at the ninth and tenth levels above the copper-bearing conglomerate lode, and at the eleventh and twelfth, which are below the lode. The thirteenth will also soon be holed through to No. 4, when the ventilation will have been considerably improved. The size of openings in these levels is also small as yet. Often they are no larger than the opening drift, or a drift and cutting out stope. As the openings grow larger the air will be better, a great improvement being noticeable in the past few months.

In no other place in the world where mining has been carried on to a depth exceeding 2000 feet is the temperature of the rocks so low as at the mines in the Michigan copper district. In some of the Comstock mines at a depth of 2000 feet the temperature is 150° above zero, and the mines of the old world after attaining a depth of over 1000 feet grow hot very rapidly. That Lake Superior, a body of water under which the rocks of the Calumet conglomerate dip, and which is only a few degrees above freezing in the summer months, absorbs the heat of the rocks is certain. That the Calumet & Hecla and Tamarack can work to far greater depth than now is certain, but just what the increase of heat will be from a depth of 5000 feet is theoretical. If one can figure by the plan being carried out at the Calumet it will be easy enough, but there is considerable speculation about it.

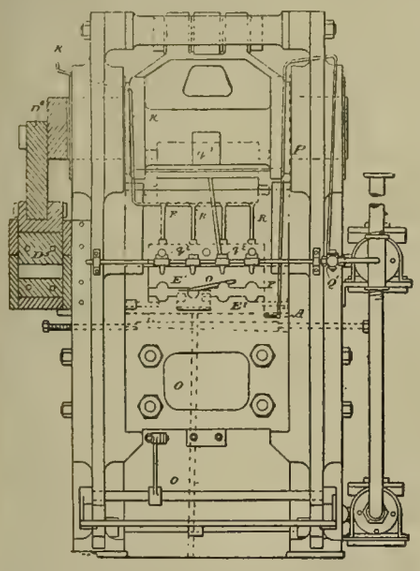
The present atmospherical condition is far from being as trying upon the miner as has been described. Many of the men working at the bottom of these shafts describe it as "being warm," but they all put in ten hours each day with machines and shovel. This they could not do if the air was as unendurable as has been represented. The men look rugged and strong, being no different in this respect from those employed nearer the surface.

There has been considerable talk indulged in concerning the holding of copper in the conglomerate at greater depths, the claim being made that it decreased as the lode extended downward. Where the Red Jacket shaft of the Calumet & Hecla Mining Co. pierced the lode at a vertical depth of 3287 feet below the surface the conglomerate had a thickness of 16 feet and was well charged with copper. At the sixty-sixth level, which has been encountered, the lode is more plentiful than at the point in levels above. Rock thus far taken out is fairly alive with copper, and will give fully 10% metal. This explodes the claim that copper decreased as the lodes went downward. At the twenty-seventh level of No. 2 shaft, Tamarack mine, richer copper is being found than for several levels above this point. The twenty-seventh is 3918 feet below the collar of the shaft. All of which goes to show that there will be both copper fit to mine and air which can be breathed for a considerably greater depth than already attained in the copper mines of this State.—Ishpeming Iron Ore.

In a paper read by Dr. H. W. Wiley, chief chemist of the Agricultural Department of the United States Government, at the joint convention of the American Chemical Society and the American Association for the Advancement of Science, in Columbus, last week, he says: "All warships under construction in the imperial navy of Russia will be armored with coffer dams packed tightly with cornstalk pith, and cornstalk pith is being sold by the United States to Russia for this purpose." Dr. Wiley also stated that he and his assistants at Washington had succeeded in manufacturing a variety of smokeless powders out of cornstalk cellulose, and finds the powders made from such cellulose far superior to those obtained from guncotton, as they keep better, burn more slowly, and are safer in every respect than the old-fashioned smokeless powders.

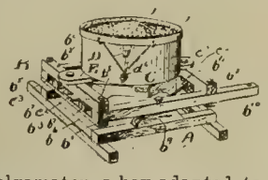
Latest Mining and Metallurgical Patents.

Patents Issued Aug. 29, 1899.



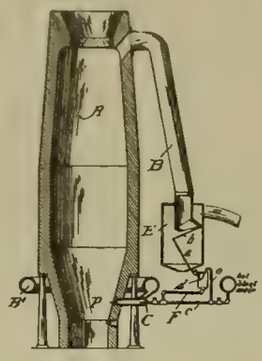
Specially Reported for the MINING AND SCIENTIFIC PRESS.

ROCK DRILL.—No. 631,787; J. Grandmaison, Lynn, Mass.



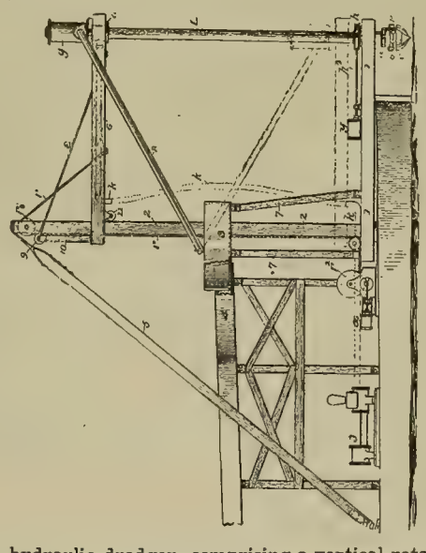
In combination with a ratchet and its pawls, a supporting disk for the ratchet, a resilient crosshead and means for supporting same, a rod or bar interposed between the outer supporting disk and crosshead, and means upon the crosshead and outer supporting disk for engaging the bar to prevent a relative rotation of the crosshead and supporting disk. The combination with the drill-receiving socket and a drill, of a tongue arranged to engage the drill in the socket, a yoke for supporting tongue, and connections between the tongue and its yoke whereby it may be advanced into the socket or retracted therefrom by a movement of the yoke.

ROCK DRILL DRESSING AND SHARPENING MACHINE.—No. 631,914; W. Wanliss, Johannesburg, South African Republic.



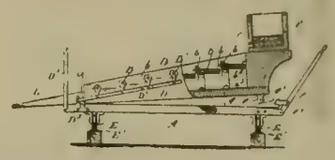
In a drill-sharpening press, the combination with the dies and operating levers therefor, of means for clearing away scale from and cooling dies, consisting of fluid jets in proximity to the dies, pipe connections for supplying fluid thereto and a valve controling the flow of the fluid with operating connections to the operating lever whereby the movement of the operating lever controls the flow of the cooling fluid. A combination with the sharpening die, of a pair of adjustable rods attached to the front of the machine, a saddle movable on rods, means for securing saddle in any desired position on the rods, and a movable gauge carried by the saddle arranged to be withdrawn when the drill is in position for sharpening to allow the drill to be moved back a desired distance before pressure of the sharpening die is exerted.

CONCENTRATING AMALGAMATOR.—No. 632,032; J. L. Wees, Oreana, Idaho.



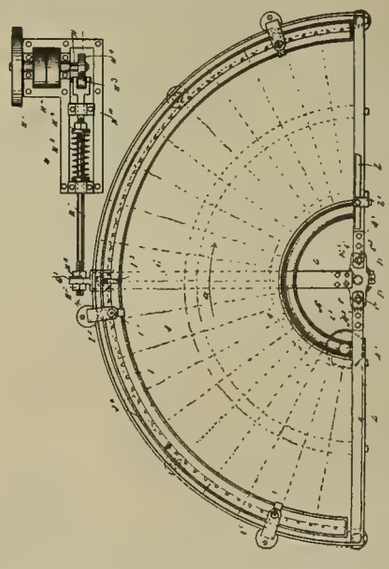
In an amalgamator, a box adapted to receive ore and amalgamate metal therein, having provision whereby the shaking of the box causes the ore to travel therein, and a frame for shaking the box, which frame is of quadrangular form, two of its sides supporting the amalgamating box and the other two being pivoted to a base, frame being adapted to change in shape whereby the box is shaken. In combination, the base A, the quadrangular shaking frame B made of four sides pivoted together, two of sides being pivoted to base, the crossbeam C pivoted to the other two sides of shaking frame, and an amalgamating box supported by crossbeam. A shaking-frame consisting of two simple beams b' b^2 and two composite beams b^3 b^4, said beams being pivoted to form a quadrangle, in combination with an amalgamator supported by two opposite beams of the frame, and a base which pivotally supports the other two beams of the frame, the crossbeam C having plates c' c^2 projecting from its ends and resting on members of the composite beams b^3 b^4, and pivot pins c^3 pivoting plates to composite beams.

BLAST FURNACE.—No. 632,147; C. S. Robinson, Sharpsville, Pa.



In combination with a furnace, a flue-dust chamber or collector connected therewith, a supplemental chamber connected with the main chamber to receive dust therefrom, means for applying pressure to the top of supplemental chamber, an injector discharging into the furnace, a source of pressure connected therewith and a pipe between the injector and the supplemental chamber. A flue leading therefrom, a dust-collecting chamber connecting with the flue, means for separating the dust and air within the collecting chamber, a supplemental chamber d connected with the main chamber to receive dust therefrom, means for applying pressure to the top of chamber d, an injector discharging into the furnace and a suction pipe between the injector and chamber d.

HYDRAULIC DREDGER.—No. 632,126; P. Kirk, Kirkland, Wash.



A hydraulic dredger, comprising a vertical rotary mast 2 with receiving box 3 and lower horizontal arm 1 rigidly connected together, an upper horizontal arm 6 braced and provided with hoisting mechanism as described and sliding vertically on the mast, the double-tube hydraulic pipe L mounted on the upper arm and provided with an inlet head a for water and a supply pipe with flexible connection, the receiving cylinder g mounted on the upper end of the inner tube of pipe L and having swiveling discharge pipe s, a ratchet collar embracing the pipe L and connected to it for a rotary movement therewith, but a vertical slip movement therethrough, and a boring head with hydraulic jet nozzle arranged on the lower end. The combination with a double-tube hydraulic pipe bearing a boring head at its lower end, and a hydraulic jet nozzle within it, pipe having an external feather running longitudinally the distance of the vertical adjustment, a ratchet collar embracing pipe and having a groove fitting the feather, and a double-acting oscillating pawl for rotating the ratchet collar and hydraulic pipe. An inlet head a having an inlet opening on one side and an annular chamber surrounding the outer tube and communicating with it, a stuffing-box at the upper end fitting the inner tube, and a stuffing-box at the lower end fitting the outer tube. The combination with an inner and outer tube; of a head block with central upwardly projecting nozzle, block being connected to the lower ends of tubes and having two sets of passages, one set communicating with the space between the tubes and the receiving end of the nozzle, and the other set alternating in position with the first set and opening from without the head laterally into the suction chamber of the nozzle and the interior of the central tube. A hydraulic boring head having lateral inlets for the dredged material made adjustable as to size and arranged to be opened by a reversal of the boring head to release obstruction.

ORE CONCENTRATOR.—No. 632,109; H. G. Grannett, Colorado Springs, Colo.

An ore concentrator, comprising a frame having a series of inclined slats therein, pivoted at their lower edges, each having a riffle extending along its pivot edge, and with its upper edge in line with the pivots, slats being placed in successively lower planes, so that the overflow from one is received by the next, and the riffles extending from the feeding end of the slats a part only of their length and being of successively greater length. Wheels under the frame, a track extending longitudinally of the slats, mechanism attached to the frame to reciprocate it, and means for simultaneously giving the slats a slight oscillating motion on their pivots. Mechanism attached to the frame to reciprocate it, cranks upon the slat pivots, a common connecting-rod for cranks, and a power connection to rod for simultaneously giving the slats a slight oscillating motion. A frame formed in two parts hinged to each other at one edge, a roller on one part at its opposite edge, a wedge block engaging roller, a lever controlling the wedge block, frame having a series of inclined slats therein, pivoted at their lower edges and each having a riffle extending along its pivot edge, and with its upper edge in line with the pivots.

CONCENTRATOR.—No. 632,075; J. C. Waters and Richard C. Waters, Romley, Colo.

In a concentrator, the combination of a table, a verticle post on which the table is mounted to swing, the table having a segmental form and having a flange at one end, the other end of the table being adapted to discharge the concentrates, a gauge mounted at other end of the table to regulate the discharge thereat, means for supporting the outer portions of the table so as to permit the movement thereof, and a curved trough extending around one edge of the table adjacent to the post, to receive the tailings. A flange secured to one edge of the table at one side of the trough, the opposite edge of the table being adapted for the discharge of the concentrates, a gauge mounted at opposite edge to control the discharge thereat, a second and curved trough located above the outer edge of the table and discharging therefrom, and a partition situated in trough to divide the same. A second curved trough located above the table at the outer edge thereof and serving to discharge upon the table, the second trough being provided with a partition dividing it into two parts.

The Concentration of Ores.*

Quartz ores contain valuable minerals, which are usually of high specific gravity: for example, galena, carrying lead, or copper pyrites, carrying copper associated with light-weight minerals: for example, quartz, calcite, etc., which are of no value.

Since the smelting process is expensive, ores that are smelted without concentration may cost more than the metal contained in them is worth. To overcome this difficulty and to substitute profit for loss, the processes of concentration of ores have been developed.

There are two steps in concentration: the breaking up of the rock to sever the valuable minerals from the quartz, and the subsequent separation of these values from the worthless portions.

For coarse breaking, Blake, Dodge and Gates crushers are used. Each machine has special qualities which adapt it to its work.

For fine crushing a great variety of machines is employed, among which are steam stamps and gravity stamps, which break the ore at a blow, and rolls and roller mills, which break the ore by rolling pressure. All of these machines find appropriate places in one or another of the mills, according to their fitness for the work to be done and the preference of the manager. For example, the gravity stamp is almost universally used for crushing gold ores; the steam stamp is the only machine now in use for crushing the native copper of the Lake Superior region; rolls are always universally employed for lead ores and sulphide copper ores; and the Huntington and Bryan mills are much used for the fine crushing of the various ores.

The preliminary separators include the grizzly, or bar screen, the drum screens (trommels), the hydraulic classifiers, and the spitzkasten. The screens separate the materials which come to them into coarse and fine, and a series of screens, with sizes ranging from very small spaces in the first screen to very large in the last, will give a series of products ranging from the finest down through all the sizes to the largest. Each of these sizes is kept separate from all the others and sent to its proper place in the treatment.

The hydraulic classifier subjects the sands which pass through the finest screen to an upward current of water in a confined space, and the particles which have sufficient weight to settle down through the current can go out through a discharge spigot below, while those which cannot do so go over and try their luck in the next pocket of the classifier, where an upward stream of less force awaits them, and so on to the third and the fourth pocket. The overflow passes on to the spitzkasten, which has three or more pointed boxes, each larger than the last; in this the particles settle from the carrying current of water which passes over the surface to the discharge end of the box, and no upward current is used. The second is wider than the first, and so drops finer particles; thus here, too, a series of graded sizes is made.

The final concentrators deliver the dressed ore ready for shipment to the smelter. These consist of picking tables, jigs, vanners, shaking tables and slime tables. They all turn out finished concentrates for the smelter. The waste, on the other hand, from the coarser machines may require recrushing to recover certain included or attached particles of the valuable minerals, called middlings, which failed to be severed from the quartz in the first crushing. These recrushed middlings are then washed again. Waste from the finer sizes is refuse.

On picking tables rich minerals above 1 inch in size may be picked out by hand for the smelter; the rest goes back to the crushers.

The jigs take the sizes next below that treated by the picking table, each of the sizes having its own jig, down to nearly the last of the classifier products. The jig treats the ore on a sieve by the action of an up-and-down movement of water. When screen-sized quartz and galena, on an immersed sieve, are subjected to an upward current of water which loosens up the ore, the galena, being the heavier, drops below the quartz, and a separation is effected. As the ore is fed continuously to the jig, the light quartz passes off by the overflow, while means are provided for drawing off from the sieve the accumulation of galena as fast as it forms.

Vanners are used to make the final separation of the last products of the classifier or the first of the spitzkasten, or both.

The slime tables, which treat the two or three last products, including the finest mud, are generally circular tables of about 17 feet in diameter, with a slight inclination from the center towards the circumference, and they revolve slowly and continuously in one direction, so that if the fine slimes from the spitzkasten are fed on one side, at the center, and clean water on the other side, the water will in both cases flow down and over the margin of the table, carrying with it the grains that are most affected by the current. The large grains of quartz are more affected than the small grains of galena, for two reasons: First, they project up higher into the water film, where the water is moving faster; and, secondly, the quartz is of less specific gravity, and, when other things are equal, it will be moved more rapidly than galena.

*Condensed from a lecture by Prof. R. H. Richards of the Massachusetts Institute of Technology, before the Society of Arts, Boston.

Note on Gold Precipitation by Zinc Dust.*

By GEORGE A. PACKARD.

It has been with interest that I have read the valuable papers and discussions appearing in the Journal of the Society during the past year relative to various methods of gold precipitation from cyanide solutions. In the United States we still adhere to the precipitation by zinc, and the one or two plants where electrical deposition has been attempted in the past, having no Von Gernet to guide them through the tortuous pathway to success, have returned to the old method. It is true we have sometimes dipped our shavings in lead acetate, when we have had copper in our ores and tailings, but so far as the writer has been concerned this has been solely for the purpose of eliminating the difficulties attendant upon the presence of copper, and not with the view of being able to precipitate from weaker solutions. Personally, with solutions down to 0.08% KCy, the writer has had no difficulty in precipitating the gold down to four or five grains (left in the solution) with the old extractor boxes, when proper attention was paid to the rate of flow and the alkalinity of the solution. We have not tackled slimes yet, and in most plants get along very well with a weak solution of the above strength.

There is, however, one innovation in the precipitation by zinc which, though possibly not unknown in South Africa, has at least escaped mention in the discussions; and that is the precipitation by zinc dust, a method which has been in practical and successful use in some of the larger plants in the United States for about three years. The method was doubtless developed from an effort to use Mr. Sulman's process of precipitation by zinc fume, but the apparatus employed bears no resemblance to that described by him in the "Journal of the Society of Chemical Industry." Probably the largest plant using this method of precipitation is that of De Lamar's Mercur mines at Mercur, Utah. This mill treats 500 tons of ore a day, the oxidized ores going direct to the tanks, after crushing, while the clayey ores are dehydrated in one roasting furnace, and the arsenic, antimony, and sulphur removed from the baser ores in others, before cyaniding. The solution from the leaching tanks, of which there are ten, 25x50x5 feet deep, passes to three storage tanks, each 20 feet in diameter and 12 feet deep. From these it is drawn into the precipitating tanks, three in number, 14 feet in diameter by 8 feet deep. Here the zinc dust is added and the solution is agitated by the admission of compressed air at the bottom of the tank. The solution is then pumped out through a filter press, and goes to the sump tanks to be used over again. At this plant the solution is not allowed to settle before pumping out, the former manager, H. A. Cohen, claiming that by lessening the time of contact with the zinc in the tanks they secure the maximum precipitation with a minimum loss of cyanide. Other managers, however, allow the dust and precipitate to settle before drawing off, and claim that the loss of cyanide is as infinitesimal as in the old zinc boxes. At the De Lamar mill there are five eighteen-frame filter presses, the frames being 24 inches square. As the pipe through which the solutions are drawn off is 8 inches above the bottom of the precipitating tanks, much of the precipitate accumulates in the bottom of the tanks and is cleaned up without going to the filter presses. Mgr. Cohen stated that the strong solution used at that time contained about 0.3% KCy, and the zinc consumption amounted to about one-fourth of a pound per ton of ore treated.

At other plants this method of precipitation has been used for solutions running as low as 0.05% KCy, containing from 3 dwts. to 5 dwts. gold per ton on going to the tanks, and showing after precipitation two grains gold per ton as the maximum. A peculiarity observed here has been that the strong solutions, containing from 0.2% to 0.25% KCy, retain more gold, averaging about five grains per ton, after precipitation, than the weaker. The most pleasant feature about this method is that all of the plants using it report that their bullion extraction fully equals their assay extraction.

Whether this method of precipitation would be of value in South Africa I cannot know, but from my own experience, in this country, with the difficulties met in treating ores carrying copper-containing minerals, and my observation of the ease with which the impurities arising from these are eliminated from the solution by zinc dust precipitation, it would seem that the method might be an improvement upon the zinc-lead process, even if it would not trench upon the field of the Siemens-Halske process.

Notes on the Occurrence of Quicksilver in Canada.*

By A. J. COLQUHOUN.

The principal quicksilver producing countries so far have been Spain, Austria, Peru, California, China, Russia, Mexico and Tuscany. These countries have all added their quota to the world's production, and I predict that in the future, when Canada has the benefit of the capital and brains required to make a financial success of the working and treatment of low-grade cinnabar ores, which has been the case in Russia and California, will take her rank among the foremost in this important industry. For the benefit of the prospector, it will not be out of place to describe the ores from which quicksilver is produced.

Cinnabar.—This is the chief ore from which nearly all the quicksilver of commerce is derived. In color the mineral is cochineal red with a lead-gray and scarlet-red tarnish, but has an unmistakable scarlet-red streak identifying it from the ochres or iron oxides, which, although brilliantly colored, often give a dullish brown streak with the penknife. The composition is 82.6% mercury and 13.8% sulphur. Native amalgam is of rare occurrence, but in the mining of quicksilver ores is met with in Mexico. Mercury iodide is also rare and is met with in Mexico, having a reddish-brown color. Selenide of mercury has been found by many of the searchers for this metal, and the writer has identified some crystals from the mercury properties of Hardie mountain, Copper creek, B. C. The ores of South America are dark steel gray in color. Cinnabar was first found about four years ago as float on the north side of Lamloops lake at Copper Creek, but, owing to the ignorance of the original finder, the specimens lay around the Savonas Hotel until an enterprising and learned prospector identified the ore, which resulted in the location of the group of claims now owned by the Cinnabar Mining Co.

The formation in which the cinnabar occurs in this section of the country consists of basaltic and dolomitic dykes traversed by veins of quartz and calcite in which the ore is found in some instances in a pure state, also finely disseminated through the gangue associated with pyrites and other foreign elements. These dykes and deposits have a general direction of N.N.W. and S.S.E. through what appears to be diabase porphyries, but it is impossible to determine the true nature, owing to the surface decomposition. To the north of the company's properties cinnabar is also found in altered conglomerate on Hardie mountain, and in fine-grained sandstone to the east on the Caledonia it is found disseminated in fine scarlet spots. Associated with the cinnabar we also find copper sulphide and carbonates, and on the Hardie mountain, as aforementioned, selenide of mercury, which invariably carries a gold and silver assay.

During my trips to the Kamloops district, last summer, I discovered a deposit of cinnabar fifteen miles south, proving the southern extension of the belt; so that, considering the Criss creek deposits to the north, we can state that the belt has been traced for thirty miles. Notwithstanding the fact of the existence of large bodies of medium furnace ore, 0.56% to 2% and over, exposed by the development of the Cinnabar Mining Co., and other deposits of high-grade ore hitherto untouched, they have not made a success. It seems a pity that, through the fault, ignorance and gross mismanagement of the concern, the whole district should be held back in its progress. About $50,000 has been thrown away in work and the erection of a furnace, tramways, etc., and has only produced 128 flasks of quicksilver; of this amount, 121 flasks were produced by means of cast iron retorts and 7 flasks by the Granza furnace.

Tuscany.—At Monte Amiata the cinnabar-bearing tufa carries from 0.35% to 30% and upward. The Carmak Spirck roasting oven is in use and is said to treat 0.4% ores at a profit. In other parts of Tuscany the ore occurs in bedded marls and limestones in a very pure state, also scattered through a network of fissures filled with calcite and averaging from 2% to 30%. Here they treat the ore by washing in rectangular boxes with rakes, and retorting the resulting mineral with an admixture of 20% lime to desulphurize and liberate the mercury.

Peru.—The famous Huancavelica cinnabar mine has given a yield of 104,045,200 pounds of mercury, valued at $67,629,380, at a cost of $10,587,000.

In conclusion, it is evident from the data given that low-grade ores, of even ½%, can be profitably worked, and British Columbia only awaits the advent of a concern which can put this latent industry on its feet again by the employment of competent men who understand the business and are capable of overcoming the many difficulties attendant on the treatment of the different grades and classes of ore to obtain the best results. The district surrounding Savona is of peculiar interest to the geologist and miner, especially the occurrence of native copper and other copper ores in the tertiaries of Copper creek, and I believe another year will see both cinnabar and copper mines in full working order.

*Condensed from transactions of the Canadian Mining Institute.

Mining Summary.

ALASKA.

Over 600 miners are reported to be successfully beach mining at Cape Nome, "making $25 a day," but so much lying has been done about that whole northern country that all statements therefrom must be doubly discounted.

The Alaska Treadwell M. Co. reports a July run of 540 stamps for 29 days, crushing 59,699 tons ore, value $94,026 and 1319 tons sulphurets, value $52,553; gross value of bullion $155,750; working expenses $48,500.

ARIZONA.

MOJAVE COUNTY.

At a depth of 300 feet the drill in the railroad company's well at Yucca encountered a seam of coal.

The Tennessee mine and mill employ fifty men. The mill is turning out thirty tons of concentrates daily.

PINAL COUNTY.

Arizona *Star*: The new cyanide plant at Mammoth will be ready for operation October 1. Workmen are putting the steel tanks together.

YAVAPAI COUNTY.

(Special Correspondence).—On the 27th of August the Eclipse Mining Co., near Jerome, sent to Prescott another bar of gold. A 5-stamp mill has been working at the Eclipse four months, during which time it is claimed $10,000 in gold has been shipped. The daily capacity of the mill is four tons. There are 300 tons of tailings at the mill which are said to average $12.

The United Verde smelter continues to extend its plant. A new refinery building is in course of construction; a new tilting furnace, another addition to the present converter building, and steel coke and coal bins are in contemplation. A 500-ton auxiliary electric crane has been ordered, making three for use in the smelter. Two locomotives have been ordered for the United Verde and Pacific Railway, narrow gauge railroad.

Surveyors are laying the pipe line from Allen's Springs to Jerome. Four miles of 4-inch and nine miles of 6-inch steel riveted pipe will be used in this line.

Jerome, Sept. 2nd, '99.

The Crowned King Company in the Bradshaw mountains, southeast of Prescott, have started their mill after a shutdown for repairs. The mine is running with a full force. The rich ore has spread through the vein. A strike is reported at the Big Belt mine. The mine has been worked and managed by R. Harrington, who has thirty men working since they put in the new hoist. They are sinking and drifting and struck the rich ore in the 300-foot level. The Star mine is owned by the Harringtons, who have a large force at work. They are drifting to cut the ledge 1000 feet below surface.

Prescott *Courier*: The Octave Company, in Weaver district, at the Johnson mine, are driving tunnels, shafts and running levels. They have, in fourteen months, made 6,000 feet of openings on the vein, and have a large quantity of ore in sight on the dumps and in the mine. They are also working on the Peterson group by contract, driving three tunnels of 1,000 feet each. On the Rumor property, the company have men sinking a shaft on the vein. There is a 10-stamp mill, which is being used to sample ores from the Leviathan and other mines on the Leviathan lead, owned by D. Genung. On this the company has twelve men sinking and drifting.——The Planet Saturn (Fool's Gulch) Company are short of water for the 10-stamp mill. Their deepest shaft is 1,000 feet.——E. Gallispie & Co. are working on the Devonshire group, owned by W. Partridge, and have a shaft down 300 feet, and are taking out shipping ore.

Prescott *Journal-Miner*: The mine formerly known as the Ridenour copper property, is now the possession of a Boston company. W. H. Ferguson, of Prescott, is superintendent. A wagon road reaches to within three miles of the camp. From there a trail descends 2,000 feet to the mines. A pack train delivers the copper ore on the platform above, whence it is hauled to the railroad and shipped to Denver. Thirty men are employed at the mine. Every shaft, tunnel and cut is on a vein of ore. The ore deposit is at a contract and averages 3 feet in width, and lies in a bed of soft limestone and sandstone. Mr. Ferguson, since April, has shipped seven carloads of ore, which has realized a net profit of from $2,100 to $2,400 per car.

YUMA COUNTY.

The output of La Fortuna mine, eighteen miles northeast of Yuma, is reported to be $75,000 monthly.

CALIFORNIA.

Amador.

The Bunker Hill Consolidated M. Co. has been incorporated at Amador City; capital stock $200,000, $5 subscribed.

Sutter Creek *Record*: The new shaft at the Kennedy is down 500 feet and progressing 22 to 23 feet a week.——The Baliol shaft at Sutter Creek is below 450 feet. Another 100 feet will be sunk before drifting is resumed and the mill started.——G. E Wallace, Supt. Alder Creek G. M. Co., will let a contract to sink 200 feet on the Gownanus claim in Plymouth district.——The Bunker Hill Con. G. M. Co. has been incorporated with a capital stock of 200,000 shares; Pres., W. F. Detert; Supt., C. R. Downs; B. F. Taylor, E. C. Voorheis, W. J. McGee. One hundred thousand shares of the capital stock go to the owners and incorporators of the mine and the balance will be sold as a working capital.——Supt. Truscott of the Oneida mine, north of Jackson, states that the north and south drifts at the 1900 level are run 125 feet in each direction on a vein 5 to 6 feet in width of fair-grade milling ore. The old shaft which was sunk in former days to 1350 feet is being pumped out and repaired. From the new shaft 400,000 gallons of water were pumped in seven days. Regarding the building of a mill, it has not been decided whether to begin upon it this fall or not. Since beginning operations, the Oneida Co. have expended $250,000.

Butte.

A. B. Chambers has thirty-five men at work on his ditch on Berry creek. When completed, work on a 40-stamp quartz mill will begin. The ledge he is developing is 100 feet wide. The ditch will carry 300 inches of water and develop power for the mill.

W. P. Hammon has negotiated a sale of dredging ground near Oroville. Two new dredgers to be operated electrically will be put thereon. Gold dredging in that vicinity has proved profitable.

Calaveras.

The Mokelumne River Dredging Co. has been incorporated in San Francisco; capital stock $10,000, all subscribed.

A recent mill test of 100 tons ore from the Melones mine, taken from the upraise, gave a value of approximately $4 per ton.

Del Norte.

Crescent City *Record*: At the Union copper mine the miners have uncovered a ledge several feet wide, and are taking out five tons of ore per day. A shipment will be made to the Selby Smelting Works near San Francisco. The last shipment yielded ten per cent copper.——The Myrtle creek hill copper prospects of McGowan & Crawford are turning out well.——In the Copper King a deposit 8 feet wide has been uncovered, and a shipment will be made. A cable has been stretched across Smith river to the county road for transferring the ore.——On the west side of Preston Peak, there are extensive mineral deposits which are being explored.

El Dorado.

Placerville *Republican*: The Placerville Slate Co. owns forty-three acres on the northern edge of Placerville, facing Big Canyon. A gravity double-track tramway is operated at an expense for water of 30 cents per day. The company is filling a large order for the Mountain Copper Co. of Shasta county, who are having all of the roofs at their plant at Keswick changed from metal roofing to slate.

Kern.

Work on the Butte mine, under the new management, is being pushed vigorously. They have struck rich ore, running as high as $2000 per ton. This ore is sacked in the mine. A few tons have been milled at the Red Dog mill in Johannesburg.

The Randsburg railroad is hauling a great deal of machinery and mining supplies, nearly all going into the Panamint country, the Slate range and the Argus country. A number of new mills are going up in these sections, and desert mining never was more prosperous than now. The men who own the mines are putting their own money into their development. One old mill building now standing in old Panamint represents, including machinery, an outlay of $100,000.

Bakersfield *Californian*: The Santa Fe is looking for cheap fuel. Boring in the Elwood well, suspended a few days ago, has been resumed. J. B. Treadwell, Southern Pacific agent, has taken a lease on the river bed across the Means ranch. This strip of ground was overlooked. The news from the Sunset and McKittrick districts is of an encouraging nature. In the latter district the Shamrock is completing a well. The oil in this well is the thinnest found. Fresno oil men visited the Sunset wells recently.

Randsburg *Miner*: The Yellow Aster mill at Randsburg is crushing 150 tons daily. The capacity has been increased lately, though no addition has been made to the number of stamps.——The Wedge mine from a clean-up of 47 tons, got $3300 a few days ago at the Red Dog mill. The ore is coming from the 200, 350 and 450-foot levels. The main shaft is down 506 feet.——There is more real dry washing being done than ever before and with good results.——It is reported that the Joyful mine will begin operations September 1st. This is one of the properties under the management of Mr. Stebbins of Ballarat.—— The main shaft in the Standford group is down 400 feet and they are sinking a winze from that level. The ore in the last milling averaged $30 per ton.

Kings.

The White Creek Oil & Mineral Co. has been incorporated at Hanford; capital stock $250,000, $96,000 subscribed.

Los Angeles.

In the Sierra Nevada mountains, near the canyon of the Tejunga, are large veins of magnetic iron ore. Similar ores occur on the summit of Mount Gleason, near gold-bearing veins, and in the Soledad canyon. The latter deposits are near the railroad, but none of them are developed.

Mariposa.

It is reported that all but about $10,000 of the $300,000 last levied on the stockholders of the Merced G. M. Co., whose mines are at Coulterville, has been paid in.

The region ten to twelve miles east of Coulterville was at one time an active mining section, and a great deal of gold was taken from the mines there. The important mines were the Martin & Walling, Banderita, Marble Spring, Ferguson, Rutherford, Cranberry, Red Cloud and Hasloe. Besides there were many of less importance but of promise. The district is reviving under the stimulus of numerous successes elsewhere and the cheapening of processes and methods.

The Hite Cove M. Co. has been incorporated; capital stock $100,000, $5 subscribed.

Mariposa *Gazette*: The Mariposa Commercial & Mining Co. have let a contract to E. Hale for 400 cords of wood. They have also purchased all the lumber of the Red Banks Co. The company have reopened 500 feet of the Pine Tree mine tunnel and have retimbered 50 feet of shaft at Princeton. Next week they expect to put men to work on the Josephine. There are large bodies of ore exposed in crosscuts on the English-Trail level of the Josephine mine, and the Princeton is but 600 feet deep, though having produced $400,000. Boarding houses are being built for the accommodation of men at the latter place, which is midway between the towns of Mariposa and Bear Valley.

Nevada.

The mining properties of P. Campbell in Yuba and Nevada counties will be sold by Court Commissioner Garthe in Nevada City next Saturday by order of the Superior Court and decree of foreclosure of mortgage for $21,727.71. J. W. Kelley of Grass Valley is the plaintiff. According to estimates the bank, which is from 150 to 200 feet in height, averages $1 per ton.

Grass Valley *Telegraph*: Good ore is being taken out of the Kentucky Ridge mine on Deer creek, near Kentucky Flat. There is a vein in the tunnel from which $35,000 has been taken. Another tunnel is being run on a 6-inch vein which will strike the main ledge at 45 feet. The mine has been paying expenses by the hand mortar process. The owners are T. A. Kohler, C. Smith, J. Castine, and Kendrick brothers.

Placer.

(Special Correspondence).—Clark & Brown have struck a rich pocket in the old California mine at Meadow Lake. Old timers say that in 1865-66 they could see the strings of gold as the ore came through the rock breaker; but, when they came to clean up the mill, they only had $2 50 total, and the camp was deserted. The black-eye the camp received at that time has stayed with it until now. Clark & Brown have taken out hundreds of dollars and are still taking out gold. There is no question but that the ores carry gold, silver and copper.

The old U. S. Grant mine, at Carlisle, at the foot of Old Man mountain, where the first gold was found in this district, and the extension, the Kentuck, have ores that will run from $12 to $30 per ton. A 3-stamp mill will be put up at Old Man mountain and will make runs for the miners. There is not a custom mill or any other mill in running order in the district.

Cisco, Sept. 1st, '99.

The Red Point drift mine near Damascus, on the Forest Hill divide, is to have a compressed air haulage plant. The power will be furnished by the water flowing from the workings, which are in 14,000 feet. The compressor will be located 660 feet lower than the mouth of the tunnel. H. C. Behr, who is the constructing engineer of this plant, figures on the development of 38 H. P. after making necessary deductions for loss. The haulage will be done by storage engines, which will be charged as often as required, along the line, which eventually will be five miles in length. Large blowers will be put in and air forced to the face. J. A. Ferguson is Supt. The compressor will be operated to 750 pounds pressure per square inch.

Colfax *Sentinel*: During the past week a 14-foot ledge has been encountered in the lower tunnel at the Herman mine on the Deadwood ridge, four miles east of Westville. From a test run in the mill it is found to yield from $25 to $40 per ton. Over 700 feet of backs can be stoped. Dr. O. L. Barton is Supt.——The ledge at the Drummond quartz mine on Shirt Tail canyon, near Forest Hill, was struck in the new lower tunnel this week. A shoot of ore in the Drummond mine returned many thousands of dollars some years ago, having been worked to a considerable depth through a shaft.——The tunnel at the Oro & Mountain View drift gravel mine, above Iowa Hill, is in 2100 feet. E. M. Armstrong is Supt.

Plumas.

W. E. Duncan Sr. has completed the hydraulic elevator at his mine.

Riverside.

F. Bates has taken the Santa Rosa mine, west of Perris, and will resume work. The main shaft is down 500 feet. The mine has a 20-stamp mill and cyanide plant. It was worked in early years by Mexicans to the water line for a distance of 1000 feet. More recently the mine was reopened and equipped but closed down after running about a year.

Thirty-five men are employed at the Gavilan mine on the San Jacinto Estate. A 10-stamp mill has been running steadily for a year.

Riverside *Press*: The Iron Chief mine, owned by Stevens Bros. of San Bernardino, has shipped bullion regularly for the past three years. It is near Eagle mountain on Colorado desert. The ledge varies from 7 to 14 feet, and is opened by a 150-foot shaft and levels. A new shaft is being sunk on the upper end of the property to connect with the old shaft by underground tunnel. They have a mill and cyanide plant and a 25-mile pipe line from Cottonwood springs to furnish the water supply. The mine is forty miles from Walters station on the Southern Pacific.——The Gold Canyon mill has been running on the ore from the mine, but owing to much flour gold a cyanide plant will be put in. The mine is eight miles from the mill, and water will be piped from the springs at Dos Palmas. The ore body is 4 to 6 feet wide, and has an average value of $17 per ton. The owners are W. A. Doran of San Diego, E. G. and G. B. Fish of San Bernardino, E. B. Stanton, E. B. Chappeller and C. C. Doran of Riverside.——About three miles east of Winchester are deposits of asbestos, magnesite and talc. This property has been developed to some extent. The asbestos is easily accessible. The magnesite deposits have been little developed.——In Menifee valley a paying industry has developed in the shipment of white quartz to Los Angeles, where it is ground and used in the manufacture of fire brick.——Mrs. Alice Crain has an antimony claim south of Winchester.

San Benito.

At the New Idria property a discovery is reported. The San Carlos part of the mine is situated a mile from the New Idria section. A tunnel in the San Carlos section was started in May and driven 300 feet until it struck vein matter. By drifting and crosscutting ore of an average higher grade than in the New Idria section has been found.

San Bernardino.

In Silver Mountain district, near Oro Grande station; at West Camp, ten miles from Oro Grande; near Fish ponds, four miles from Daggett; in Panimint range, and near Resting springs are silver-lead ores. Some of these prospects are of promise, but have little development. The most extensive development is in the Resting springs district.

The Tecopa M. & S. Co., a Los Angeles corporation, proposes to resume work on the Tecopa mine, ninety miles from Vanderbilt.

San Diego.

At the Stonewall mine, Julian district, eighteen men are working over the tailings.

The kaolin deposit in El Cajon mountain, twenty miles east of San Diego, has been bonded by G Holcomb for $100,000. A 95-foot shaft is locally reported to pass through 85 feet of a kaolin deposit. Kaolin is worth $19 per ton in eastern markets.

Santa Barbara.

Santa Barbara *Press*: Mr. Cody of Montecito is drilling an oil well on property recently purchased by him on the beach at Miramar.

Los Angeles *Herald*: A strike of semi-liquid asphaltum has been made at the P. C. Higgins rancho in Carpinteria. A deep oil well was being bored there, but at a depth of 1250 feet a stream of asphaltum was tapped. Nothing was thought of this at first, but now the thing is serious in more than one way. The first strike was made three weeks ago. At that time the asphaltum rose a few feet in the 5½ inch pipe. But since then $2000 has been expended in efforts to drill, but not once has a drill touched bottom. At 10 o'clock Tuesday night the asphaltum stood 40 feet deep in the well, but Wednesday morning it rose rapidly, and at 8 o'clock the depth was 160 feet. The asphaltum is like soft mush and will need little or no refining. It is worth $30 per ton. The questions now are how to get the asphaltum out of the well and how to keep on boring. The well is the only one of the kind about there. Mr. Humphreys, Montecito, who has sold land on the beach for oil rights, says no compromise could be made, as money had passed between him and the oil men on the transaction. He also said that he had between 800 and 900 feet more of similarly located land. Mr. Humphrey sold Cody & Nelson, who have made themselves prominent by pushing the matter of oil drilling on the beach.

Shasta.

J. Wilson has made a strike 6 miles west of Furnaceville. The rock is rich, $200 being taken out the day following the discovery.

George Barber of the Buckeye region has taken from a small streak in the ledge of the Cleveland mine some very rich quartz. The Cleveland is in the Quartz Hill region, near the original Quartz Hill mine and is the property of W. M. Hiatt.

The sale of the Gold King quartz mine in Mule Mountain section was consummated last week through A. G. Boggs, J. B. Cooke of Colusa buying the mine from J. G. McDaniel. There is a shaft, tunnel and several drifts on the property. The ledge carries quartz and ochre.

It is locally reported that Lewisohn Bros. of New York City are to give up their bond on the Golinsky-Clendenin property in the Backbone district, being the result of the visit of J. P. Channing, the representative of the firm, who does not believe the result of the development will justify the purchase of the property at $160,000. Work is discontinued. The property is on the sulphide belt in the Backbone district and consists of 320 acres of land.

Redding *Free Press*: Captain J. R. DeLamar has bought from J. W. and T. M. Popejoy the Hogue-Worley water ditch and rights. The ditch takes water from the west side of Horse creek in the vicinity of Copper City.

Sierra.

United States Circuit Judge Morrow on the 6th in San Francisco rendered a decision in the case of Henry Skinner, plaintiff, against the Garnett G. M. Co., defendant. Skinner is a miner and was employed by the defendant company in its property at Hepsidian. Skinner and forty-one other employes, whose claims were assigned to the plaintiff, worked for the company from January 1 to December 14, 1897, without any pay and sued for $3981.50 with interest and $500 attorney's fees. The case was taken to the Circuit Court, as the corporation is organized under the laws of the State of West Virginia. Judge Morrow, in his decision, allowed the claim of the plaintiff.

Siskiyou.

Eastern capitalists, through Mr. Monroe, are bonding and purchasing a large group of gravel claims on Beaver creek. An appropriation of 20,000 miners' inches of water of the creek has been made and the work of ditch construction is to be commenced.

The Siskiyou Gold & Copper M. Co., which has acquired title to a group of fifteen claims, including the Mabel mine, at the head of McKiney creek, have been surveying the group. One and a half miles of road has been completed from the group to the mill site. The development work in the four tunnels is progressing and ore of high grade extracted.

Mining machinery is being conveyed to the property.

The Wheeler & Russell mine employs seven men. The vein, though small, is rich. The owners talk of the erection of a milling plant before winter.

The Little Tiger property, consisting of seven claims, adjoining the Cape mine, recently completed a survey of the property. The two crosscut tunnels are being extended and the mill started up on Monday.

The Doney mine has been bonded by an Eastern syndicate, represented by F. Leich.

Rose & Nightkirk are engaged transporting their new mill to their property on Ash creek.

At their mine on Sterling mountain Brown & Argle have taken out $5000 this season. The largest piece of gold was worth $300.

Another shoot of high-grade ore has been found in the mine of Miner & Co.

A rich vein of free-gold ore has been exposed at the Cherry Hill mine.

The crosscut tunnel at the Little Wonder mine, owned by Ironsides & Wadsworth, has been extended 300 feet in.

The Schroder mine shows an increased value of sulphide ores, and the mill has been shut down awaiting the addition of a concentration equipment.

Yreka *News*: The Davis group of eight claims, six miles southwest of Montague, has been sold by the owners to Dr. G. W. Dwinnell of Montague for $41,000. The deposit or vein, as far as uncovered, is 40 feet wide, has a northeast course and outcrop for 300 feet in length. The ore is decomposed and consists of sulphide of lead, iron and copper with arsenic. The development work consists of a shaft 25 feet and a tunnel 40 feet, the face of which is high-grade ore.——The owners of the Knownothing mine have bonded their property to G. W. Grayson of San Francisco. Mr. Stanley is Supt. It is the intention to sink the shaft 100 feet and then put up hoisting equipment.——Rich ore is being extracted from the Lanky Bob. One arrastra is being run.——At the Brown Bear mine developing work is proceeding.——A vein 3 feet in width has been discovered by Mr. George near the King Solomon mine. The force employed is twenty-five, and the mill is crushing pay ore. During Mr. Fletcher's absence Mr. Bowerman is acting Supt.——At the Carlock & Morrison mine a concentrating plant has been built. The vein is 17 inches wide.——At the Gray Eagle mine the main working shaft is being sunk 100 feet.——An adit from the Turk ground is to be run 500 feet to connect with the shaft. The mill has five stamps and an addition is contemplated.

Yreka *Journal*: In the Oro Fino and Quartz Valley mining districts quartz mining is active. Two mills are running, one at the Morrison ledge and the other at the Thornton ledge. Turner, who is opening the Allen mine, is taking out fine quartz, and will put up a mill. Men are scarce and the companies have been obliged to send away for help.——G. W. Foote, who recently secured the Merrimac mine on Humbug, has found the ledge again, which contains rich quartz, 4 inches in width.——The miners at the Golden Star or Spencer mine have struck the ledge at the old works, to which a new lower tunnel has been run. The directors of the company have levied another assessment, it is supposed, to put up a mill for crushing at Humbug.——Considerable work is in progress on quartz mines in the Ash creek section of Cottonwood mining district, on Klamath river, below Hornbrook. A road has been built up the creek, including branch roads, and a great amount of prospecting has been carried on.

Trinity.

The Copper Hill, four miles west of the Cleveland Con., was bought two months ago by Dr. M. M. Shearer and four others. Seven men are at work. A tunnel driven 100 feet below the croppings has reached a depth of 70 feet. Reports from Selby show 12% copper, with gold and a small quantity of silver.

Watson & Foster of the Globe mill recently discovered a ledge 18 inches in width that extends 150 feet on the Van Matre gulch side of the ridge, four miles below the Globe. The assays run $40 to $150 per ton.

Tuolumne.

American Camp district is in the northwest corner of the county, about 10 miles from Columbia. The formation of the district is mica schist, grano-diorite quartzite, limestone and other metamorphic rocks. The veins are from a few inches to several feet wide and carry a high grade of sulphide ores beside free gold. Owing to lack of roads and rugged character of the country the development has been retarded.

At the Santa Ysabel mine, Quartz mountain, the upraise between the 4th and 5th levels is developed 40 feet, and the ore is improving in grade. In the drift on the 5th level the ore has widened to 15 feet.

Union-Democrat: At the Dreisam mine, at Arrastraville, sinking has been discontinued and the mill is crushing ore from the 200 level taken from the Yellow Jacket shoot. It is high grade and free milling. From the crosscut tunnel the quartz has been drifted 200 feet.——A rich body of ore is reported to have been opened in the Grizzly, near Carters. The gouge has turned to quartz, which carries free gold.——The working shaft of the Goldwin has reached a depth of 215 feet, with sinking progressing. The vein is 5 feet wide in the bottom, worth $8 per ton.——At the Buchanan, south of Carters, sinking on the north vein was discontinued at 700 feet, and miners are driving a crosscut for the Buchanan vein. This vein is large.

Yolo.

A San Francisco company is putting in a large plant and will soon begin sinking oil wells on Sulphur creek.

COLORADO.

BOULDER COUNTY.

A deal was closed at Denver on the 6th inst. by which an English syndicate purchases for $2,500,000 cash the properties of the Big Five Mining Company at Ward. The properties include the Niwot, Dewdrop, Columbia and other well-known gold producers.

At the Giles mine leasers are taking out good ore from the 250 east level and the company is running a crosscut south from the 450 level.

The Puzzler Mill management are contemplating enlarging the mill and treating custom ore.

The Struggler shaft has been put in shape and sinking commenced. Two eight-hour shifts are working, which will be increased to three.

CLEAR CREEK COUNTY.

Idaho Springs *Gazette*: The owners of the Chamberlain at a depth of 30 feet have a 4-foot vein of milling ore that will run $10 per ton, and a 6-inch streak on the foot wall that will run $150 per ton in gold. This property lies at timber line on Chesapeake mountain, and the vein will be cut at a depth of 800 feet in the Chesapeake tunnel. Paralleling the Chamberlain is the Great Divide, which has been prospected. The vein is 10 to 12 feet wide and assays at 60 feet $2.50 to $15 per ton in gold and silver. The Chesapeake tunnel will also cut this vein at a depth of 1000 feet. West of Chesapeake mountain on Alice mountain are large veins of low-grade ore. The most promising is a vein 20 feet wide that assays $10 per ton gold. The Aureo lode has a shaft 40 feet deep on a 5-foot vein. These locations belong to a Pueblo company, which will do extensive development work.

DOLORES COUNTY.

Rico *News-Sun*: J. M. Hall and J. D. Clarke, who are working the Hope on Nigger Baby hill, have in the breast of the drift a 3-foot vein of spar impregnated with copper and galena.——Crecelius & Ditchfield have out half a carload of manganese ore. They are working the Cobbler vein of the Pittsburg property.——J. Spurlock has a new vein on the Grand View which shows manganese ore.——McGill, Jolley and Hughes have a 2-foot vein of high-grade gold-silver ore on their Newman lease.——The Saw Pit Gold Mining and Milling Co. filed location notices on the Seymour Nos. 1, 2, 3 and 4 lodes, Saw Pit placer and a mill site. The company will build a mill.

Rico *News-Sun*: The Saw Pit M. & M. Co. has ordered the machinery for its new power plant and mill to be erected in Navajo basin. The county will co-operate with the Saw Pit Co. in the construction of a wagon road from the meadows into the basin.——During August the mines of Rico shipped fifty-eight carloads of high-grade ore, making a total since the beginning of the year of 282 cars.

GILPIN COUNTY.

Central City *Register-Call*: A deed has been recorded conveying from E. C. Lindemann to the Lindemann Tunnel M. & M. Co. the Lindemann tunnel, on the south slope of Stewart mountain, Hawkeye district.——In the Perigo section there are five stamp mills in operation.——In Gamble gulch men working under lease have been successful in sluicing. The water supply this season has permitted sluicing operations on a larger scale and for a longer period than in former years.——Fifteen men are working in the Gold Dirt mine, on the 500 east and west levels, where a good sized body of ore is opened. Daily shipments of mill ore amounting to thirty tons are going to the Perigo mill in Gamble gulch and the Peterson mill in Lump gulch. Jenkins, Lightbourn & Co. have let a contract to sink a shaft east of the Gold Dirt shaft.——The War Eagle is being subleased from the Tonawanda Leasing & M. Co. by W. C. Stanley, who is making shipments to the Stanley mill in Lump gulch.——At the Perigo fifty men are employed, the miners working on the subleasing system. The leasers are taking out ore to keep twenty-five fast-drop stamps supplied in the Perigo mill, a tonnage of 75 tons per day.——E. C. Lindemann is running the Douglas mill at Wide Awake, keeping twenty slow-drop stamps going on oxidized ores from the Lindemann Nos. 1, 2 and 3.——At the Stewart mine the retimbering of the shaft is under way.——Prof. Lindemann has started up the Lindemann tunnel. The tunnel is being run from Stewart gulch to cut the Stewart vein. The tunnel is in 70 feet and Mr. Lindemann will put in an air compressor. Three veins have already been cut.——W. Kelly and G. Kanarum of Black Hawk have taken a three-year lease and bond on the Kentucky Belle claim, in Gregory district. The shaft is 80 feet deep. Machinery will be put in to expedite developments.——G. W. Mabee is sinking a shaft on the Linden, on Gunnell hill. The shaft is down 65 feet and the machinery, formerly on the Baxter, is being installed.——Sinking operations at the Cook mine, on Bobtail hill, are in progress. The shaft is down 830 feet. It will be put down to 1000 feet. One hundred men are at work.——Mgr. H. P. Lowe of the Topeka mine reports that during the week the working force will be increased. A new and larger plant of machinery will be installed, consisting of a 120 H. P. gear hoister, two 80 H. P. boilers and a six air drill compressor.

GUNNISON COUNTY.

Gunnison *News*: The Carbonate is making a steady output of eight tons of ore daily. A small dyke or "horse" has been replaced by ore.——The ore of the Whopper is being concentrated at the Scofield mill. There is a hundred tons on the dump. The Scofield concentrator has been running for a week on ore from La Plata, Burt and other properties. Plans are being projected to put in power that will enable work to be continued through winter.——The Black Queen mine is reported sold under contract to W. Miller of New York, and H. P. Barbour of Denver. The sale includes the Black Queen, Fargo, Legacy and Last Chance. The three first named are patented. The plans of the new management embrace equipping the mine with machinery and a concentrating mill is to be built, the mine and mill connected by a tramway, and a new power plant put in.

LAKE COUNTY.

Carbonate *Chronicle*: At the Hibschle shaft on the S. Small millsite, Leadville, F. Schmidt is superintending developments. The shaft is in the parting quartzite 100 feet, and sinking to get into the white lime. No exploration in this horizon has been done in this section of the camp. The shaft is 300 feet deep.——Geo. W. Cook has returned from Chicago. He has contracts for all the manganese that Leadville can produce, and states that shipments would be increased as much as possible. At the Chip property on Fryer hill preparations are being made for a large output of manganese. The new plant is in position. The manganese comes from the 200 level.——The Lent shaft of the Seneca, under lease to Col. Cook and Mr. Parker, is operating at the 120 level. They have plenty of manganese in sight, and are making shipments.——Drifting continues from the 1100 level of the Greenback, and the drift will be continued to the Mahala line where air connection can be made. The Greenback is making some water, which is handled without interfering with the hoisting. The shaft is arranged for two cages, and one of these is fitted with a tank carrying 300 gallons of water. It is sent down into the sump. This enables 150 gallons per minute to be hoisted 1,100 feet at a cost less than pumping. The bailing operations do not interfere with the regular working of the mine.——The Maid of Erin and Henriett tonnage for August will reach 3,000 tons, which includes oxidized iron, lead carbonate, iron and copper sulphides and zinc. There are twenty sets of lessees on the ground; most of them are shipping. The Maid and Henriett mine was at one time abandoned.——The Resurrection has started work on its new shaft in the Big Evans flat. It is a three-compartment shaft, 4½x13. A plant of machinery will be placed in position.

MINERAL COUNTY.

Silver Plume *Standard*: Creede is active again. The large shippers have put on men and are making increases daily. Miners laid off because of the strike are being put back to work. Ore shipments are double what they were two weeks ago.——The Mollie S. is being worked regularly.——Attention is being directed towards Sunnyside. All available properties have been leased and development is going on. Since the improvement in Corsair ore attention has been given other mines on McKenzie mountain.——The Amethyst has a new hoisting plant, boiler, etc. A number of men recently laid off have been put back to work.——The Commodore is mining 125 tons per day and clearing its bins of ore stored there during suspension.——Bachelor No. 2 has made its first shipment since the close down.

MONTROSE COUNTY.

Prof. Paulet, chemist for the Rare Metals M. Co. of Denver, has gone to Paradox, where the company has bought a uranium mine and started work.

Denver *Mining Record*: The Huntsman Copper Mining Co. announce the discovery of a new ore body in the lower tunnel being run to crosscut the original discovery 200 feet distant. At a depth of 100 feet they have a new body of ore, the values of which equals that being shipped from the upper workings.——L. Antles and G. R. Propper, owners of the Corsair group at the head of Miner's basin, have a 6-foot vein of copper and gold ore that averages $8 in gold and 20% copper.——In Mill Creek basin Denver men are to erect a 20-stamp mill. They have two free milling veins.

OURAY COUNTY.

Ouray *Herald*: The Rare Metals Mining & Manufacturing Co. of Denver have, through their agent, A. Lamson, secured leases on a number of wolframite prospects, also on a mill for concentrating the ore. L. Arbi will be in charge of the mill at Gladstone, San Juan Co., and Mr. Lamson will have charge of the mining. Both wolframite and huburnite are found near Gladstone.

SAN MIGUEL COUNTY.

Ophir *Mail*: J. H. Brink, one of the owners of the Gertrude group, states that the principal work is a tunnel 800 feet long, starting on the Saginaw and running through the Gertrude and Gold Standard. Plans have been made for the erection of a mill, including pipe line and flume. The pipe line will be 1,000 feet in length and the flume 2,000 feet. The fall will be 257 feet.

Telluride *Journal*: The Palmyra group of claims has been sold to the Four Metals Company, of which J. Morton of Pueblo is general manager. The Palmyra group includes the Palmyra, the St. Julien, the St. Louis, the Maud S. and the Como lodes, with two mill sites, upon which are two small lakes, affording good water facilities; the surface ground is covered with timber. It is estimated that there are 20,000 tons in sight. Throughout the workings the ore has an average width of 3 feet. The ore carries gold, silver, copper and lead, and numerous mill runs of several hundred tons show the ore to run on an average $16 per ton. The new owners will extend the tunnel 500 feet farther, which will give them a depth on the vein of 1,500 feet. The Four Metals Company will erect a large concentrating and amalgamating plant and an air compressor, to be operated by electricity taken from the wires of the Telluride Power Transmission Company.

SUMMIT COUNTY.

Breckenridge *Journal*: The Cashier gold mine is located in Brown's gulch and consists of four claims. It has a large body of low-grade ore, developed by two 350-foot tunnels, one above the other. They are connected by a winze. The company is building a mill for treating the ore. The mill will have twenty quick-drop stamps and a provision made for the addition of twenty more. The mill will have a capacity of eighty tons per twenty-four hours.

TELLER COUNTY.

Dr. S. R. Bartlett has the Fleming, on the west slope of Bull Hill. The purchase price is reported at $12,000. Two tunnels have been driven on the property 800 and 400 feet, respectively, and several small shafts have been sunk, the main one 50 feet. A number of veins have been opened up, but for the most part low grade. At the bottom of the shaft a vein has been opened which runs $40 to the ton.

The insurance losses by the Victor fire were distributed among forty-five companies, no company losing more than $25,000.

The total gold output of Cripple Creek for August was 33,650 tons of ore, value $1,328,000.

New strikes in the Cripple Creek region are of almost daily occurrence. Some of them are in well developed mines, the finds being made in the course of regular development, and in some cases are anticipated, but the greater number are made by leasers at comparatively shallow depths. The work being done tends to show that a preconceived idea of the value or worthlessness of any particular part of the mining territory is not based upon conditions as they are proven to exist, and that a vigorous policy must be maintained in prospecting.

The Herrington lease on block 1 of the Hart group has opened a large body of ore and it is thought they have one of the Damon veins. The strike was made at a depth of 50 feet.

The second strike of pay ore has been made in the Golconda in the crosscut from the bottom of the shaft at 433 feet. The vein is 2½ feet wide and averages $25 per ton. A plant of machinery is on the way and consists of a 50 H. P. gasoline engine, air compressor and drills. The Golconda is under lease and bond for four years to the Philadelphia & Pittsburg G. M. Co.

Victor *Record*: Attention is being paid to Signal and Gold Quartz hills, some distance west of what has thus far been considered the gold belt. On the Ollie claim, located on Signal, and owned by the Ollie G. M. Co. of Creston, Iowa, a shaft has been sunk 115 feet.——Fifty tons of mill-grade ore are being sent daily to the cyanide plants from the Granite mine, on the south slope of Battle mountain. Large ore bins are being built.——During August 1000 tons of ore, averaging $40, was sent from the Keith & Grube lease on the Vindicator.——A carload of ore, assaying ten ounces per ton, is being sent daily from the Wallace mine at Independence.——Twenty tons of medium-grade ore were sent out recently from the Huff lease on the E. Porter Gold King. It went to the National sampler at Goldfield.——From the Independence mine, during August, 3000 tons of ore, valued at $256,000, were shipped.——The Columbia claim, sold by Reed & Eaton, will go to a company at Colorado Springs.——It is reported that the Margaret, north of the Pinnacle, has struck a body of ore 5 feet wide that will run $150 per ton.——Within a day or two work will be started on the fifth level in the Jack Pot at a depth of 483 feet. The fourth level was driven 100 feet above. The total output of the mine for August was $100,000.

IDAHO.

ADA COUNTY.

The receipts of gold at the Boise United States Assay Office during August were larger than for any other month in the history of the office, the total being $243,820.

BLAINE COUNTY.

At Hailey the Crœsus shaft is to be sunk to the 1000-foot level, the single compartment being enlarged to a double compartment from the present 450-foot level to the surface.

Hailey *Times*: A Boston company will take water from the Malad river, near its mouth, and pipe it across the Snake for placer mining on the south bank of that river. The undertaking will cost $100,000. It is said they have good property. Surveyors have already been over the route making preliminary surveys.

CUSTER COUNTY.

It is reported that in the Lucky Boy mine at Custer, the ore has been encountered, according to survey, on the 800 level. The company is controlled by W. S. McCornick, N. Treweek and A. Hanauer of Salt Lake. It gives the company 200 feet of stoping ground along the dip of the vein in which the ore shoot varies from 5 to 15 feet. Twenty stamps are dropping. In thirty days, Col. Treweek says, the battery will have been increased to thirty stamps. In the meantime the new cyanide plant, through which 1400 tons of tailings are to pass under the direction of M. Bamberger, is approaching completion, while the tramway to the mill will be ready in a few days.

IDAHO COUNTY.

Spokesman-Review: Men from the new camps on Snake river report that recent developments have opened large deposits of sulphide copper ores on both sides of the river in the Imnaha district. A large body of ore was found on the Delta group last week. A ledge 40 feet wide was exposed in a contact deposit that cuts the mountain for half a mile. The Delta group is bonded to the Exploration Copper Co., composed of New York men, represented by L. Eaves.

Weiser *Signal*: E. P. Emerson of Baker City has deeded to the Boston & Seven Devils M. Co. the Little Idaho, Eighty-Eight, Copper Dyke, Harvard, Bodie Fraction, Admiral Dewey, and one-third of Bob Fitzsimmons mines, water right on Deep creek located by J. Walton, and the Massachusetts mill site. The deed bears $685 in revenue stamps, though the consideration named is but $1. Add Colo

OWYHEE COUNTY.

The Hoosier Mining Co., near Silver City, proposes putting in a cyanide plant.

A new stamp mill is to be built at the Cumberland mine, on War Eagle mountain. Jas. Shaw is manager.

An important mining enterprise, known as

the Sinker creek tunnel project, is to be started. This tunnel is to cut through War Eagle mountain from a point on Sinker creek. It is stated that R. J. Anderson, representing Philadelphia capital, has secured agreements with the owners and will run the tunnel. He has made contracts for the purchase of most the claims, and work on the tunnel will begin within thirty days. The War Eagle mines are among the richest in the State. They all closed down at the time of the California Bank failure and have never been started up since. California people were formerly the principal owners. The tunnel, which will be several thousand feet in length, will cut the mountain 2500 feet deep and 1000 feet below the deepest workings of the mines.

SHOSHONE COUNTY.

Colorado miners are arriving at Mullen by the carload.

MICHIGAN.

HOUGHTON COUNTY.

The Calumet & Hecla Co. have started sinking the fifth shaft on the Osceola lode.

MISSOURI.

JASPER COUNTY.

The value of the output of ore in Joplin district for last week was $230,141, zinc ore $45, lead ore $27. The Chitwood Hollow land, the property of the United Zinc & Lead Co., led the district in production last week.

There was produced by the New York Zinc Co. in the six days ended August 26, 184,000 pounds of zinc ore and 24,000 pounds of lead ore.

Joplin reports that the combination among zinc miners there to demand $46 per ton for ore carrying 60% of metal will be fought by refineries. Representatives of several large concerns are now in Colorado contracting for a supply of ore, which will enter into competition with the Missouri product, with presumably favorable freight arrangements with railways.

The American Zinc, Lead & Smelting Co. have purchased the Center Valley lease together with seventy acres in fee, for $191,000.

MONTANA.

CARBON COUNTY.

At Carbonado the Carbon Coal Co. has taken up its mine tracks and pulled the pumps. The company suspended coal mining three months ago, but a diamond drill was put to work and the announcement made that mining operations would be resumed Sept. 1, with a reduced scale of wages. The members of the Carbonado Miners' Union held a meeting and voted not to accept the reduction in wages, and work was not resumed.

DEER LODGE COUNTY.

The Gold Coin properties and mill employ sixty men. The company has acquired six additional claims and is securing patents for them.

GRANITE COUNTY.

Butte *Miner*: J. F. Boyd, a watchman at the Granite-Bimetallic mines, has been arrested charged with stealing $50,000 in silver bullion during the past fourteen months.——Galvanized iron pipe is being made for the Granite-Bimetallic Co. at Granite, which is to be used in the mill for carrying the dust from the battery to a bin, doing away with the dust and saving silver. This is an experiment by the company in a portion of the mill to give it a test. A pipe extends from each mortar to the floor above, where it is connected with a larger pipe, into which the dust is sucked by a blower.

LEWIS AND CLARKE COUNTY.

At the Belmont mine, near Marysville, J. H. Longmaid is Gen. Mgr. and Supt., and F. Longmaid foreman. The mine has been opened by four tunnels on Belmont mountain, all of them aggregating 1½ miles in length, with a depth of 500 feet. The ore is free milling gold quartz and averages $8 per ton. The formation is granite, with intrusive dykes of porphyry. Preparations are being made to sink on the vein, and a station for the hoist underground is complete, 500 feet from the mouth of the lower tunnel. The hoist will have a capacity for sinking 500 feet and raising 100 tons of ore per day. Two 50 H. P. boilers will furnish steam. The mill is being erected. The power for running the 20-stamp mill and cyanide plant is furnished by a separate 100 H. P. engine and boilers. Seventy men are employed in the mine and thirty in the cyanide and stamp mill—100 in all. One hundred tons of ore per day are treated; 60% of the gold is saved on the plates, the tailings flowing to vats, where they are settled and removed to the cyanide vats. As soon as a sufficient supply of water can be obtained, these tanks will be flushed. All the water used in the mill comes from the mine. There are 11,000 tons of tailings in the sand dump.

SILVER BOW COUNTY.

In digging a basement for a building in Butte, R. Rochester struck a vein which gave assays of $100 in silver and $100 in gold to the ton. In the first week Mr. Rochester made $1700 and has more than paid for the cost of the building. In excavating the cellar for the Thornton block, corner of Broadway and Wyoming, a lead of rich ore was uncovered. The old miners say it is the richest lead ever shown in Butte at the top of the ground. The find is above the Smokehouse lode. J. A. Murray of the newly organized Smokehouse Co. wants to sink an inclined shaft on the vein.

A flume is being built from Storm lake to Silver lake for the Anaconda Co. to secure an increased water supply. The source of Silver lake has been found to be Storm lake, but water was lost through seepage. It is to obviate this that the flume is designed. It will be fourteen miles in length.

It is proposed now to start up the Parrot plant to work tailings of the Parrot Co. Tailings have been accumulating for years, some of them very rich. It is believed tailings will average 5% copper besides other metals, and will keep concentrators going for three years.

NEVADA.

LINCOLN COUNTY.

The management of the April Fool Mining Co. at De La Mar, headed by W. Thompson of Butte, will enlarge the mill.

LYON COUNTY.

The first tank of the Logan and Hulley cyanide plant, in Como, is filled. The tailings are from the Logan and Hulley mine, and contain from $10 to $12 in gold.

STOREY COUNTY.

The Truckee River General Electric Co. has finally closed contracts with the Comstock companies, north and south, for electrical power to be furnished the mines on substantially the same basis as that already published—$7 per H. P. The company is building a paper mill at Floriston, Cal., 400 yards west of the Nevada line, and has acquired title to four miles on both sides of the Truckee river. It proposes to build a large power plant to furnish light and power for the paper mill, the Comstock lode, and the towns of Reno, Carson and Virginia City. H. Fleishhacker, San Francisco, is the secretary.

WHITE PINE COUNTY.

The gold dust sent to Salt Lake from the Ely Mining Co.'s mill gives a valuation of $62 per pound.

NEW MEXICO.

COLFAX COUNTY.

The Memphis mine of Bitter creek had a successful run on its ore at the Confidence mill at Elizabethtown. The concentrates are very rich and Mr. Pooler will negotiate for a plant to concentrate the product at the mine.

GRANT COUNTY.

The Cleveland group of five mines at Pinos Altos was sold on the 6th inst. by G. H. Utter of Silver City to H. D. Selleck of New York City for $50,000.

SAN JUAN COUNTY.

Nineteen teams of horses and mules passed through Mancos last week, hauling mining machinery and supplies for the placer grounds on the lower San Juan river. The gold to be saved "is of the finest flour."

SANTA FE COUNTY.

In the case of the New Mexico Mining Company, Judge McFie has discharged Receiver Elkins and approved his report. The New Mexico Mining Company is owner of the Ortiz mining grant, twenty-five miles from Santa Fe. The grant was confirmed by act of Congress, March 1, 1861, for 69,000 acres. Of the original grant 15,026 acres were sold to the Cerrillos Coal & Iron Co., leaving 54,000 acres in the grant as now constituted. S. H. Elkins was appointed receiver of the grant in May, '96. He now turns the property over to S. G. Burn, who takes charge of the property in the interest of Thomas A. Edison, who is reported to be the purchaser of the property for about $3,000,000. It is stated to be Mr. Edison's intention to build a large reduction plant, at which to treat the gold ore from the new Ortiz mines by his new electric process.

TAOS COUNTY.

Santa Fe *New Mexican*: The Ester is one of a group of six claims near Red River which are owned by J. M. & G. L. Moad, L. E. Wade and P. B. Coffelt. They are considering the erection of reduction works in connection with their properties. The ores are copper, gold and silver.

OREGON.

BAKER COUNTY.

Baker City calls for a United States assay office and makes a showing that justifies the demand.

JACKSON COUNTY.

The Ashland quartz mine, near Ashland City, is sold to Montreal and Spokane men. The company is incorporated as the Montreal & Oregon Gold Mines and will commence development work. H. Mattern is local manager until October 1st. C. G. Griffith is managing director. The selling price is reported to be about $120,000.

The Gold Bug Mining Co., Mount Ruben, is reported to have sold its properties to C. D. Lane and A. Hayward of San Francisco, a ninety-day bond for $1,000,000 being given, with an initial payment of $100,000. The property was owned by J. P. Jones of Nevada. There is a 5-stamp mill in operation. The report is locally denied.

JOSEPHINE COUNTY.

G. F. Wheeler of Grant's Pass, receiver of the Siskiyou Copper M. Co., operating near Waldo, says that the carload of copper ore shipped to the Selby Smelting Works at San Francisco turned out so well that 100 tons more will be shipped to the same establishment as soon as possible.

SOUTH DAKOTA.

(Special Correspondence).—The Carr mine, discovered last May by two cowboys out hunting cattle, has been sold to N. Treweek and associates through the agency of E. C. Johnson of the Mining Exchange at Hill City, S. D. The property comprises 130 acres, with mill site, water right, timber, etc, and is located eight miles southwest of Custer, in Nugget gulch. This is the richest free gold strike ever made in the Black Hills. The ore averages $1360 gold per ton, after the specimens have been picked out. Charles Carr was attracted one afternoon by a red "blowout" 50 feet above, on the side of the gulch, and examined it. He broke a piece of rock and saw what looked like a kernel of yellow corn imbedded in the quartz. He concluded it was gold. He and his brother borrowed picks and shovels and returned the next day and opened up the ledge. Subsequent development has opened several other rich veins 3 to 5 feet in width. Indications seem to show the probability of a very large ore body below. Soon after being discovered the property was sold for $125,000. The purchaser was unable to meet the deferred payments and the sale was not consummated. Nicholas Treweek, the purchaser, has been foreman of the Homestake mine for the past seventeen years. The future services of Mr. Treweek have been secured by a syndicate of Chicago capitalists, who during the past year have drained the underground lake in the Uncle Sam mine on Elk creek, famous as a producer fifteen years ago, and have developed it into a rich free gold mine.

Custer, S. D., Sept. 1st, '99.

LAWRENCE COUNTY.

The Golden Reward chlorination works, recently destroyed at Deadwood by fire, are to be rebuilt, with double the capacity of the former plant. A plan to fit the new works for both chlorination and cyanide is being considered by the company. A fourth furnace has been blown in at the pyritic smelter, formerly Deadwood & Delaware, but now owned by the Golden Reward Co.

UTAH.

IRON COUNTY.

A good strike is reported in the Ophir, at Stateline. In the west drift ore has been encountered that shows seventy ounces silver, with gold. It is the intention of the owners to equip the proposition with machinery, including a steam hoist.

JUAB COUNTY.

The Centennial-Eureka mine, recently sold, has paid $2,130,000 in dividends. It is reported that there is in sight in the mine ore worth $5,000,000, gross value.

J. H. Stallings, Supt. of the Tesora at Silver City, reports that the water is under control, and the management will sink the shaft another 100 feet, at which point drifting will commence. The high-grade shoot of copper sulphides varies from 20 inches to 3 feet in width, showing 18% to 36% copper, 26 ounces silver and $2 gold.

E. P. Jennings, Supt. Dragon Iron mine, at Tintic, reports the new shaft down 240 feet. At 500 feet drifting underlying the iron outcrop will commence. At the Alaska, of which Mr. Jennings is also Supt., drifting is now going on both ways from the shaft.

The Sacramento M. Co.'s steam hoisting and ventilating plant has been supplanted by electricity. The new plant was used for the first time on the 3d inst.

Pres. Merrill of the South Sunbeam mine at Silver City reports a strike in that property. A vein of ore 4 feet thick has been cut, which assays 50 to 100 ounces in silver and some gold. Before the main vein was encountered three or four stringers were struck. Large quantities of mineralized and whitish talc have been uncovered. The owners propose putting in, as quickly as possible, pumping and other machinery.

Tribune: The management of the Grand Central at Tintic has an arrangement with the Bingham Copper and Gold Mining Co. at Bingham that will afford the former a market for its low grade silicious ores that, with the Bingham sulphides, makes a perfect smelting combination. In the Grand Central, the ores constitute a milling proposition, with good auriferous values and some silver. Under the arrangement these may now go without alteration to the smelter that will be erected by the Bingham Copper and Gold Mining Co. Of the silicious ores there is a large volume. A site will be selected for the proposed smelter this week and the plans now in the hands of Mr. Walters will be submitted in a few days.

SALT LAKE COUNTY.

Engineer Fisher, who drafted the plans for the Highland Boy smelter, is working on the plans for the smelter to be located upon the property of the Santa Fe M. Co.

In the development and exploration of Galena ground, the shaft is to be sunk 200 feet. It is now down 125 feet, to which depth it is being enlarged and retimbered. A steel gallows frame will be put up.

A large number of copper mining locations have been made on Antelope island, in Great Salt Lake, and assays are high. It is claimed that a wide mineralized ledge can be traced the entire length of the island, which is fourteen miles long.

Bingham *Bulletin*: A strong flow of water was struck at the Kremlin group Monday. A new pump will be necessary. The 200 level is in 200 feet ore.——At the De Lamar-Wall group concentration operations have been completed. Everything cleaned up, the concentrates shipped and the men paid off. The mill has been closed and turned over to its owners, Rogers & Sons, who expect to start it up on ore from some of the United States Company's holdings on which they have a lease. How long the close-down at the De Lamar-Wall will last is not known.

TOOELE COUNTY.

The Mercur mill will be increased to 600 tons daily capacity.

It is reported that important discoveries have recently been made in the Geyser-Marion.

SUMMIT COUNTY.

Float was picked up near Park City last week which was assayed by W. D. Clays at Bingham, giving the following: No. 1, 12,890 ounces silver and $12 gold; No. 2, 1526 ounces silver, $2 20 gold and 12 5% copper.

Park *Record*: The Daly-West mill has closed down for repairs. Two new jigs have been put in and other improvements made to increase the output.——At the Ontario the work of rebuilding the furnace has commenced and the mill put in readiness to resume work on Ontario ore.——The sinking of a 500-foot shaft on the Putnam ground has commenced under the supervision of D. C. McLaughlin.——Ore hauling to the old Anchor concentrator has ceased, and, after a cleanup, the machinery will stop and the mill will be dismantled. The machinery will be taken to the new mill, where it will be used in connection with the new machinery.——The Weber & Kearns mill is through with its work and hereafter the Silver King mill will take the ores that have kept the former mill in operation.——The mines of the Park district ship 1500 tons of ore weekly.

WASHINGTON.

In Okanogan and Stevens counties nearly a thousand teams are reported hauling freight from the head of navigation on the Columbia river to the Methow, Okanogan, Slate Creek, Camp McKinney, Republic and Colville mining districts, from 40 to 102 miles, the latter being the distance to the Camp McKinney mines, across the boundary in British Columbia. Considerable development is on the Colville reservation, thrown open two years ago.

OKANOGAN COUNTY.

The 10-stamp mill of the Okanogan G. M. Co. is running. Mgr. Edgecomb of Loomis figures that he can mine and mill the ore by the cyanide process for $2 per ton. The company owns the Similkameen Falls, and proposes to use them in generating electric power.

Mgr. Boyd of the Palmer Mountain tunnel has received instructions to put a double shift on the tunnel, increasing his force to nearly fifty men. The big No. 12 ledge will be drifted on east and west, and other drifts will be continued with day and night shifts. Mr. May is considering machinery for reducing and treating the ores.

FERRY COUNTY.

It is reported the Republic M. Co. will build a custom mill.

The Princess Maud, in the winze, which has been sunk 125 feet, has a body of ore that runs $125 to the ton. There are streaks of sylvanite in the vein which runs $1400 in gold and silver to the ton.

The Northwest smelter has made a rate of $4.50 per ton for freight and treatment to the Rossland, B. C., mine owners. The Trail, B. C., smelter rate has been $6.

WISCONSIN.

There will be an increase in the output of the zinc mines in the southern part of the State. The Mineral Point Zinc Co. is building new furnaces and putting in new equipment of hoisting machinery, preparatory to extending its workings. The oldest zinc mines in the west are in this district, and though some of them have been operated in an indifferent fashion for years, the present demand for metals has caused a revival and led to the investment of new capital.

FOREIGN.

BRITISH COLUMBIA.

(Special Correspondence) —Redman & Outhett have prepared an exhibit of the Kamloops district ores for the Paris Exposition. The exhibit consists of gold, silver, copper, lead, molybdenite, cinnabar and iron ores. The Board of Trade is having an exhibit prepared for the Spokane Fair. N. C. Wallace of Toronto is expected in Kamloops to look over the Iron Mask with a view of resuming work thereon. Mr. Nastell of Tacoma, Wash., has resumed work on the Cyclone mine, five miles south of Kamloops. The Glen Iron mines at Cherry Creek, thirteen miles west of Kamloops, have been bonded to a Pittsburg syndicate. Shipments of ore from the Gordon claims are being made to the Trail smelter. The Cinnabar mines on Hardie mountain, on the north side of Kamloops lake, are being worked under superintendency of J. F. Wells. The ore averages 2% quicksilver. The company intends erecting furnaces. O. S. Batchelor has bought Mr. Dillon's interest in the Last Rose of Summer. The sale of the Chieftan group of copper-gold properties on Coal Hill to the Mines Contract and Investigation Co. of Toronto is reported. The same company has a bond through J. T. Robinson on A. Noble's Pole Star. H. Bostock has purchased the Drayman from Jas. Blair.

Kamloops, B. C., Sept. 1st, '99.

A smelter of fifty tons daily capacity has begun work at Van Anda, on Texada Island. There is great activity on the island and the neighboring coast, and the district will this year for the first time add to the metal yield of the province.

Smelting and transportation charges have been reduced to a figure so low that $10 ore will now afford a profit to Rossland miners.

MEXICO.

A Mexican paper tells of "the uncovering of a solid mountain of native ferro-nickel manganese at Durango." "Tradition has it that this enormous mass of native metal is an aerolite that fell from the sky centuries ago. It is more than 300 feet high, half a mile wide and more than a mile in length, and is estimated to contain more than 500,000,000 tons above ground. It is worth $480 a ton." A pretty story.

SOUTH AFRICA.

During the month of June the output of the Witwatersrand was as follows:

	Ozs.	Dwts.	Value.
From Mill	38,690	4	£1,051,099
Concentrates, etc	11,161	7	37,182
Tailings	139,469	7	470,189
Slimes	8,658	8	30,183
Banks	784	5	2,700
Total	445,763	11	£1,591,353

GENERAL SUMMARY.

	Ozs.	Dwts.	Value.
Witwatersrand	445,763	11	£1,591,353
Lydenberg	10,117	11	34,821
De Kapp	8,532	13	30,679

THE YUKON.

There are no new discoveries around Dawson, and the old ones are being worked out. The properties are passing into the hands of aggregated capital, and considerable machinery is going in. The newest steam thawer is reported a success.

Industrial Notes.

—Stockton is now the electrical city of California.

—A telephone line from Denver, Colo., to Cheyenne, Wyo., is now in operation.

—Steel rails have again advanced to the following prices: New York $32, Chicago $31, Pittsburg $30.

—The customs receipts at San Francisco for August were $758,601.63, the largest amount ever received.

—Eighteen miles of heavy narrow gauge road will be built this season from Morenci to Guthrie, Arizona.

—Jerome, Arizona, proposes to spend $60,000 for water from the Verdi river. The water is to be raised 900 feet.

—The United States for its Asiatic mails last year paid $23,000 to American steamships and $14,000 to foreign steamships.

—It is reported that the Carnegie Co. in the last few days withdrew offers on structural iron and steel and advanced prices $5.

—Oil has been discovered ten miles southwest of Trinidad, Colo., and a company has been formed in Colorado Springs to develop it.

—The Nevada Power Co. has organized at Reno, Nev., to transmit power from a canyon east of Reno to the Comstock for pumping, etc.

—The Utah Valley Ry. Co. will extend its electric line from Salt Lake City to Bingham, power to be had from the Telluride Co., Provo.

—The Cripple Creek Railway Co., capital stock $1,000,000, has organized at Denver, Colo., to build a railroad from Canyon City to Cripple Creek, thence to Denver.

—W. S. French of Alma and W. S. Wilson of England, who own the W. C. ranch near Alma, N. M., have bought 120,000 acres of the Maxwell land grant. The price paid per acre is 70 cents.

—The proposed establishment of fortnightly American mail service from San Francisco to Shanghai would bring Berlin and Paris within twenty-eight or twenty-nine days of Shanghai.

—Under present industrial conditions a tin mine would be of greatest value. North America is the greatest consumer of tin, yet there is no producing tin mine of any consequence in its entire area.

—Paymasters in the Philippines have asked for shipment to them of coin instead of notes, alleging that the ants of that country had almost entirely destroyed $300,000 in paper money. During the last year more than $7,000,000 has been paid to the soldiers in the Philippines.

—President J. C. Osgood, of the Colorado Fuel & Iron Co., says that the steel works at Pueblo will be enlarged, probably to three times the present producing capacity. The C. F. & I. Co. will increase its capitalization from $13,000,000 to $25,000,000 at a meeting called for on the 25th, at Pueblo.

—The Telluride Power Transmission Co., owning the electric plant at Provo, Utah, purposes to increase the plant and to double the power. When the Provo plant was first constructed the company generated 1200 H. P., but this was doubled shortly after it was in operation. Before the company increased its capacity, every bit of the increase of power was engaged and contracted for, and the works at present are crowded to their full capacity. The water power which operates the plant has an energy of 6000 H. P., and it is the intention of the company to go to the limit. The company has gone into the development of electric power very extensively and have several plants in Colorado, Utah and Montana. The plant is operating mills at Mercur, thirty-five miles away, and the highest voltage known—40,000 volts—is utilized to transmit the power.

—The Colorado Electric Power Co. has a contract with the Woods Investment Co. to run a 258 H. P. motor in the new Economic Gold Extraction mill at Victor, erected by E. Woods, until the Economic Extraction Co. can install generators of its own. The company also has a contract with the Arequa sampling works mill, near the Elkton mine in Arequa gulch, for 250 H. P. These two concerns are the largest users of electricity in that district. Other large users are the Taylor & Brunton sampler, 75 H. P.; the Cripple Creek sampler, 50 H. P.; Rio Grande sampler, 50 H. P.; Tornado mine, 75 H. P. compressor; Lillie mine, 100 H. P. compressor; Moon-Anchor, 100 H. P. motor of electrical pump; Damon, Wildhorse, Blue Bird, Los Angeles, Ingham, Matoa, Lafayette, each 30 H. P. hoists; Deadwood, 15 H. P. hoist; Gold King, 10 H. P. hoist.

—Statistical information regarding the manufacturing industries of San Francisco shows that during the year ending March 1st, '99, the number of manufactories was 1846, the number of employes 32,104, and the value of the product for the twelve months named was $77,189,116. Among others there are 5 manufacturers of air compressors; employes, 80; value, $300,000; artificial stone, 31; employes, 310; value, $400,000; architectural iron, 7; employes, 70; value, $175,000; barbed wire and wire nails, 2; employes, 75; value, $110,000; belting, 9; employes, 45; value, $160,000; brass foundries, 10; employes, 400; value, $850,000; car, 4; employes, 80; value, $150,000; coppersmiths, 12; employes, 50; value, $100,000; cordage and rope, 2; employes, 250; value, $700,000; electrical machines, 3; employes, 200; value, $250,000; electric lighting companies, 5; employes, 600; incandescent lights, 100,000; arc lights, 5000; horse-power and motors, 10,000; coal used annually, 50,000 tons; value of products, $2,000,000; electric supply, 17; employes, 160; value, $310,000; elevator, 3; employes, 80; value, $150,000; foundries and machine shops, 40; employes, 4000; value, $5,000,000; gas works, 3; employes, 1000; value, $3,000,000; gas engine, 5; employes, 150; value, $150,000; glass works, 25; employes, 175; value, $1,300,000; iron fence, 4; employes, 22; value, $40,000; japanning and galvanizing, 3; employes, 40; value, $110,000; jewelry and silverware, 29; employes, 162; value, $805,000; lead pipe and shot, 1; employes, 50; value, $500,000; linseed oil, 1; employes, 60; value, $170,000; marble works, 26; employes, 100; value, $100,000; paint, 7; employes, 65; value, $575,000; pumping machinery, 11; employes, 60; value, $210,000; rolling mill, 1; employes, 30; value, $100,000; shipyards, 6; employes, 400; value, $1,500,000; solder and babbit, 3; employes, 35; value, $80,000; type foundries, 3; employes, 110; value, $70,000; wire and wire rope, 2; employes, 200; value, $1,000,000; water wheel, 2; employes, 60; value, $275,000.

Personal.

TAYLOR D. MCLEOD of Yuma is in Los Angeles, Cal.

JAS. D. HAGUE has left Nevada Co., Cal., for New York City.

JAS. FARRELL is the new superintendent Red Line Group, B. C.

BERNARD MACDONALD is examining mining property at Rossland, B. C.

A. W. TENNANT of Santa Fe has bought the Cerrillos, N. M., smelter.

F. F. THOMAS, superintendent Gwin mine, Cal., is visiting San Francisco.

EDGAR P. RATHBONE announces his future headquarters will be Cascade, B. C.

GEORGE MITCHELL, of the Cobre Grande, Cananea group, Mexico, is in New York.

R. A. JONES succeeds W. R. Jones as superintendent of Gold Bug mines, Glendale, Or.

DR. THOS. BOYSON of the Kennedy, Cal., mine, has returned from Virginia City, Nev.

PAUL JOHNSON is still examining smelter sites between Midway and Boundary Falls, B. C.

G. H. EVANS has returned to Breckenridge, Colo., after a brief business visit to San Francisco.

F. H. DEAN of Cripple Creek, Colo., is in San Francisco looking for California mining investments.

H. M. CROWTHER will have charge of J. R. De Lamar's Gold Mountain mine in San Bernardino Co., Cal.

GEO. A. RICE, of London, England, has recently been investigating the copper mines of Shasta county, Cal.

W. M. KELLY succeeds P. Y. Murphy as superintendent of the Anaconda C. M. Co.'s lower works smelter.

MARK E. CAREY has returned to Albany, Or., with $25,000, the result of seven years' effort in South Africa.

CAPT. DE LAMAR this week goes to Bully Hill, Shasta county, Cal., to inspect his newly acquired copper property.

BERT HALL is at Ballarat, San Bernardino Co., Cal., operating the mill and cyanide plant for the Jail Canyon Co.

GEORGE W. HULL, at one time owner of nearly the entire Jerome, Arizona, townsite, is in the East on legal business.

J. H. LEWIS, has gone to London to bring the attention of the Government to the claims of American miners on Atlin lake.

CHAS. F. HOFFMAN, an Oakland, Cal., mining engineer, is expected back from West Australia, via London, next week.

J. H. MCKENZIE has been appointed manager of the Mariposa Commercial and M. Co., vice Capt. Thomas Mein, resigned.

J. H. HURSTE, of Kingston, N. M., has gone to Magdelena, Mexico, to take charge of the mining company's operations there.

JOS. LEITER, of Chicago, is in Colorado, and is there credited with intention to "corner" the asphaltum industry of that State.

JNO. F. MCDONNELL has been re-elected for the thirteenth time financial and recording secretary of Virginia City, Nevada, Miners' Union.

F. A. PROVOT, mine engineer of the United Verde Copper Co. at Jerome, Arizona, is again at his post after a severe siege of typhoid fever.

H. M. GORHAM, superintendent of the Cholar, Potosi, Savage and Crown Point mines at Virginia City, Nev., is at Santa Monica, Cal., convalescent.

J. W. NEILL, of the U. S. M. Co., has returned to Salt Lake City, from Butte, Montana, where he gave expert testimony in the Parrott suit.

MESSRS. CORAM AND HOLMES, who recently bought the Garner group, Calaveras county, Cal., have come to San Francisco from Boston to see their property.

C. H. MACKINTOSH, of Rossland, B. C., formerly Governor of the Northwest Territories, a prominent mining man, is in San Francisco with a view to buying mining properties.

EDWARD HARDACK, who has been in South Africa for five years, has been appointed to a position with the Simner & Jack M. Co., near Johannesburg, at a stated salary of $20,000 per year.

SECRETARY HAY has sent instructions to the American Consul at Pretoria, directing him to protect all American citizens and interests in case of war between Great Britain and the Transvaal.

W. S. KEYES of San Francisco goes to Butte, Montana, next week to give expert testimony in the Parrott suit. R. W. Raymond and Clarence King will also testify, the case lasting through September.

A. F. HOLDEN, of the U. S. Mining Co., will be manager of the Centennial-Eureka, Utah, property. When the Centennial-Eureka option was secured, $2,400,000 worth of ore was blocked out. The U. S. Co. will build a smelter of 800 tons daily capacity.

F. W. PECK, the commissioner-general of the United States at the Paris Exposition, has the endorsement and support of the mine owners and business men of Colorado Springs and Cripple Creek, Colo., in his project to send the Paris exhibition a pyramid of gold bullion worth $1,000,000.

A. J. WALSH of Butte Co., Cal., is now in charge of the Evans hydraulic elevator work at the Risdon Iron Works, San Francisco. During a recent inter-mountain trip, Mr. Walsh installed six Evans hydraulic elevators at Breckenridge, Colo., one at Ingold placer mine, Boulder Co., Colo., and two at Wyoming gold mine, Dubois, Wyoming.

A. EKMAN, who is preparing California's mineral exhibit at the Paris Exposition, says the exhibit will be a fine one; that as space is limited only the finest specimens from California's mines will be shown and that, except a few small cases of specimens of particular interest and merit, the exhibit will form a part of the national mineral exhibit.

FRED C. MATHYAS, who for several years has been a field assistant of the State Mining Bureau, has been appointed to collect the mineral exhibit to be made by the Southern Pacific Railroad Company, in connection with a display of the resources of the State of California, at the Paris Exposition in 1900, which will be under the direction of W. H. Mills of the land department of the company. The company will erect a special building for this display, which will include all the resources of the State, agricultural as well as mineral.

Notices of Recent Patents.

Among the patents recently obtained through Dewey, Strong & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

MORTUARY MONUMENT.—W. A. Hawthorne, Chittenden, Cal. No. 631,890. Dated Aug. 29, 1899. This invention relates to a device for indicating the last resting place of deceased individuals, and a means connected therewith for containing the ashes of the deceased person when cremation has taken place. It may also be so arranged as to exhibit a counterfeit presentment of the face or figure of the person of the deceased. It consists of a base having a vertical tubular standard supported thereon, and tubular arms connected with the upper end of the standard having end caps adapted to receive medallions, the tubular portion also serving as a container for the ashes when desired.

VAPORIZOR.—M. L. Cooper, Modesto, Cal. No. 631,952. Dated Aug. 29, 1899. The object of this invention is to provide an apparatus for heating air and to vaporize such substances as it may be desired to apply or distribute in such a condition. It consists of a hollow casing with inlet and outlet pipes and a closed chamber with partitions, forming a sinuous passage through which the air is transmitted, a heater beneath said chamber; a flexible, non-conducting conveying pipe, through which the heated air is transmitted to the point of application, a holder connected therewith and nozzles applicable to the end of the holder, with an interposed non-conducting section to prevent the heating of the holder.

List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey, Strong & Co., Pioneer Patent Solicitors for Pacific Coast.

FOR THE WEEK ENDING AUGUST 29, 1899.

631,932.—BIT STOCK—W. L. Baumgardner, Watsonville, Cal.
632,098.—MACHINE GUN—E. M. Capps, San Diego, Cal.
632,044.—EGG BEATER—S. E. Chapman, Napa, Cal.
631,952.—VAPORIZER—M. L. Cooper, Modesto, Cal.
631,847.—RAILROAD TRACK CLEANER—Dart & McMurry, Seattle, Wash.
632,110.—RUBBER CEMENT—M. B. Grout, North Yakima, Wash.
631,890.—MONUMENT—W. A. Hawthorne, Chittenden, Cal.
632,126.—DREDGER—P. Kirk, Kirkland, Wash.
632,128.—WATCH PLATE—E. Krabenbuhl, San Rafael, Cal.
632,222.—BOX—V. M. Malatesta, S. F.
632,194.—ELEVATOR—A. W. Morey, Owyhee, Ogn.
631,939.—ENVELOPE—Nellie P. Pakard, Centralia, Wash.
632,227.—HAMMER—C. E. Perry, S. F.
631,968.—FIRE ESCAPE—D. B. Rees, Union, Ogn.
631,835.—SHOE JACK—H. Waters, Bisbee, A. T.

NOTE.—Plain and Certified Copies of U. S. and Foreign patents obtained by Dewey, Strong & Co., by mail or telegraphic order. American and Foreign patents secured, and general patent business transacted with perfect security, at reasonable rates, and in the shortest possible time.

Catalogues Received.

IN green and gold comes Catalogue No. 33 of the M. C. Bullock Manufacturing Co., Chicago, devoted entirely to the diamond drill as manufactured by the Bullock Manufacturing Co., minutely described in technical detail, profusely illustrated with prices, descriptions and explanation of everything in connection therewith. The instructions for operating diamond drills, setting diamond bits, etc., are of practical value to any present or prospective owner of one of those valuable mining appliances. A copy will be sent to any address upon request by the M. C. Bullock Manufacturing Co., Chicago, Ill.

CATALOGUE No. 12. Hercules Gas Engine Works, 305 Market Street, San Francisco, Cal.: A handy little pamphlet copiously illustrated and giving details of hoisting engines made for miners by the manufacturers of the Hercules gas and gasoline engines, with testimonials from satisfied purchasers. The catalogue will be sent free to any address.

Books Received.

"*Heat and Heat Engines.*" A study of the principles which underlie the mechanical engineering of a power plant; by F. R. Hutten; 8vo. xxi. and 553 pages; cloth, $5; profusely illustrated; John Wiley & Sons, New York. The scope of this work is an ambitious one and appears to be comprehensively treated. The book is of unusual merit and deserves the following from the preface, which indicates its character and value:

"The effort has been made under another title, 'The Mechanical Engineering of Power Plants,' to discuss the steam-engine and the steam boiler with their accessory apparatus, so as to enable students and others to make an intelligent selection of successful designs for a set of conditions which might be imposed. The object of the author was to make the reader familiar with accepted solutions of the power-house problem in all its details, but no attempt was made to discuss the questions of design of such apparatus. It was intended that the student should ask at the end of his study of that book: What are the principles of physics and dynamics upon which these machines depend; and how do engineers proceed when called upon to design such power-house engines?

"This book, under the title of 'Heat and Heat Engines,' has been prepared to answer these questions in part. It discusses the energy resident in fuels, and the methods of its liberation as heat for power purposes; the transfer of such heat to convenient media whereby it can be used in heat engines; the laws and properties of such media, and the design of cylinders of the necessary volume to give a desired mechanical effect or horsepower. Then, this point having been reached, and relations being established for the mutual variations of temperature with pressure and volume in such media when operated in a cylinder with a piston, it becomes easy and natural to go further and discuss the air compressor and its compliment, the air engine; and to extend this discussion to include the problem of mechanical refrigeration. The hot-air engine using a permanent gas as a medium naturally leads to the gas engine and the oil engine; and the engine using steam as a medium leads naturally to those other media, such as naphtha, alcohol and ammonia. The chapter on the Injector as a heat-absorbing and energy-transforming device closes the book.

* * * * * * *

"This treatise tries to occupy a middle ground. It might wisely be used as a groundwork for subsequent treatment of heat phenomena by the analytic or mathematical method after the student has become familiar with the physical facts of which the equations of thermodynamics are condensed statements.

* * * * * * *

"This is the result of trying to treat thermodynamics without the calculus, and the result should be to turn the student to further and exhaustive research in the higher field. At least, this is the author's desire.

"Equations could not be avoided, nor the use of logarithms; but the use of the temperature-entropy diagram for the graphical representation of relations has been abundantly permitted. The appendices also open doors into departments of further research and knowledge beyond the scope set by the limits of the text."

Commercial Paragraphs.

GEO. E WOODBURY will move from 141-143 First street to 223 First street, San Francisco, Cal., on the 15th inst.

THE Mine & Smelter Supply Co. of Denver, Colo. has a contract with the Diamond R. M. Co. of Neihart, Montana, for a 100-ton concentrator.

AT Hanover, N. M., a large Gates crusher, requiring two railroad cars to transport it, has been received by the Colorado Iron & Fuel Co.

THE Risdon Iron Works of San Francisco have an order for pumps, hoisting works and other machinery from the Boston & Seven Devils Copper Co.'s South Peacock mine, Cuprum, Idaho.

THE Cochrane feed water heater and purifier, and the Cochrane separator are meeting with great success. Parke & Lacy, 23 Fremont street, San Francisco, are the Pacific Coast agents.

THE Denver Engineering Works Co., Denver, Colo., are building and equipping a mill for the Mountain Pride, Colo., G. M. Co., to be operated by steam, and one for the Ault-Viberg, Colo., Co., to be operated by electricity.

Recently Declared Mining Dividends.

T. F. T. M. Co., Cripple Creek, Colo., $35,000; Sept. 5.

Swansea M. Co., Tintic district, Utah, $5000; Sept. 9.

South Swansea, Tintic district, Utah, $7500; Sept. 5.

Sacramento M. Co., Utah, $5000; Sept. 1. Total, $133,000.

Raven M. Co., Cripple Creek, Colo., $10,000; payable Sept 20.

Empire State-Idaho M. & D. Co., 2½% (an increase of ½%); payable Sept. 15.

Montana Ore Purchasing Co., extra dividend, $1 per share; payable Sept. 27.

Breece Iron M. Co., Leadville, Colo., 5 cents per share, $10,000; Sept. 1. Total under Penn Co. lease $30,000.

Mead G. M. & M. Co., regular quarterly dividend No. 4, at the rate of 40% per annum on issued stock of the company; payable Sept. 11.

Boston & California G. M. & M. Co., regular quarterly dividend No. 3, at the rate of 6% per annum on issued stock of the company; payable Sept. 15.

Broken Hill Sulphides.

By CLEM. A. HACK.

One of the most difficult and seductive problems of the last few years has been that of the economical treatment of refractory sulphide ores at Broken Hill, New South Wales. As the stores of oxidized ores have been reduced the various mines have been compelled to fall back upon the sulphides, which are found in enormous quantities. Much time, energy and money have been expended in endeavoring to devise a process by which these ores may be economically treated, so as to pay for for their raising. Numerous suggestions have been made for treating this class of ore in the crude state direct, the most notable of which are the Turner and Ashcroft processes, but none of these have been proved upon a commercial scale. It has been found that it is best to first subject the ore to exhaustive concentration, whereby the percentages of the richer minerals are largely increased, while those of the deleterious are decreased, so as to render the ore more suitable for smelting. It is, therefore, to this mechanical concentration, and not to the chemical treatment, that the mine manager looks more particularly for improvement and invention to enable him to lower his working expenses, and thus cheapen his treatment of the ore.

The crude ore, as raised from the mine, consists of a mixture of galena, blende, rhodonite, garnet and gangue. The galena is the most valuable, being a sulphide of lead, and carries the silver; the blende is sulphide of zinc, containing a small percentage of iron; garnet and rhodonite are silicates of iron, manganese, etc., while the gangue is mostly quartz. The mechanical treatment at Broken Hill is carried out in jigs, and depends for separation upon the difference in the specific gravity of the various materials contained. The products from this treatment are concentrates containing most of the galena, with a much lower percentage of blende, rhodonite, garnet and gangue; middlings of blende, rhodonite, garnet and a percentage of galena; and tailings of gangue with other materials in varying quantities. As regards the concentrates, the chief difficulty is the presence of the zinc as blende, for this greatly interferes with the smelting, and the object sought is to eliminate the zinc to such an extent as not to exceed 10% to 15%.

But the zinc blende itself is about the same specific gravity as the rhodonite, and these two, therefore, are usually found together in the concentrator products. It is the presence of this rhodonite occurring with the blende in such quantities that renders the zinc up to the present practically untreatable. There are thus to be seen at Broken Hill large dumps of these products, containing valuable metals, awaiting the ingenuity of some intelligent reader to suggest a suitable method of treatment.

Great interest has lately centered round a proposed method of treating these products by means of magnetic separators. These magnetic machines, of various patterns and designs, have long been known in America and Europe, but have been confined more particularly to the treatment of low-grade iron ores. The idea is not in itself new, for as far back as 1792 a patent was granted to a Mr. W. Fularton for the separation of magnetic material from non-magnetic, by subjecting them to the influence of magnets, but this was long before the advent of electro-magnets. Great success has attended the efforts of P. J. Weatherill, of New Jersey, in the treatment of low-grade iron ores, and he has found that by the application of wedge-shaped pole pieces he is enabled to obtain a magnetic field of such great intensity that materials thought before to be non-magnetic become susceptible in varying degrees to the lines of magnetic force. These wedge-shaped pole pieces act somewhat in the same manner as a nozzle to a hose, and serve to condense the lines of magnetic force. By subjecting the material to magnetic fields of varying intensity fractional separation has been obtained of the different constituents, according to their degree of magnetic susceptibility. Thus it has been found that rhodonite can be separated from blende, and blende from quartz or gangue, and it is to magnetic separation that we are now hopefully looking for a successful solution of the problem whereby large bodies of zincy products may be worked up to a sufficient richness in zinc to be worth treating. But it is in the commercial treatment upon a large scale that the greater difficulties are generally met with. The distance through which the lines of magnetic force extend their influence is very small indeed, and therefore the line of demarcation between the separator products is correspondingly small, and must be capable of very fine adjustment. Further, the ore must be fed into the magnetic field in such a manner that there will be very little other force exerted against and contrary to that of the magnets. The ore must also be fed in such a way that all the particles will come directly under the influence of the field within which they must be retained as long as possible. Besides, the products must be delivered into their respective hoppers continuously, so that there will be no clogging, and the magnets will be always free to exert their influence. It is to these last mechanical details that the attention of the inventive public is earnestly invited.

Railroad Building by Music.

A wise foreman of a construction gang of Southern darkies knows that he can get about 50% more work out of them if he can keep them singing, when the picks and shovels will invariably keep time with the music. The same custom seems to prevail among the African aborigines.

Building a railroad in the Soudan is not carried on to the sound of the voice of an Irish "boss" directing a gang of Italian laborers. As becomes the milder atmosphere of the tropics, a railroad in those regions is built to the "lascivious pleasing of a lute" or the African equivalent. The "sofas" are the working people, and the "griots" are the musical ones. The "sofas" will not work unless the "griots" play. So every gang of men has its orchestra. The "griots" play on flutes and rude harps the peculiar "rag time" tunes of Africa, and the picks and shovels of the "sofas" go industriously as long as the music lasts. In the Soudan it has been found impossible to get work out of the natives in the construction of railroads unless music was furnished.

To every gang of forty or fifty men there are assigned two harp players and a flute player. As long as the music keeps up the black laborers do not seem to feel fatigue. Generally the musicians get tired before the laborers do. The music produced by these cheerers of labor would not be inspiring to a white man, for it is filled with peculiar plaintiveness. To the Africans, however, the tunes seem to be an inspiration. To the sound of music the steel rails are penetrating the Congo region and forcing their way through the Soudan.

A case somewhat similar to this is the custom in the Cuban tobacco factories. In the big room where the cigar makers work is always a reader. He sits up on a platform and reads novels to the workmen as they manipulate the tobacco. Again, on board ship a sailor will work as well again if he is permitted to "shanty"—that is, sing a working song, the rhythm of which keeps time to his labor. But in the building of railroads music is a new factor. Cecil Rhodes' "Cairo to the Cape" road will be literally fifed and harped through Africa.

WITHIN a few miles of New York City last week, in less than nine minutes, the engineers of the Pennsylvania Railroad removed the draw of an iron bridge across the Passaic river weighing about 500 tons and replaced it with a new one of steel that weighs 1000 tons.

Abuse of Machinery.

"There would be fewer kicks about mining machinery," said an old-time machinery salesman, "if the purchasers would treat it properly, but the fact is there are too many successful miners who think that, because they have been successful, they know it all, and in saving the salary of a competent man lose many times as much as they save. You would be astonished to learn how many intelligent miners go to pieces when it comes to machinery. They seem to forget that the parts of a machine are fitted together accurately on a perfectly level base, and if they do not have a solid foundation they are sure to come to grief.

"I never sell a compressor, even of the smallest size, that I do not insist upon a solid cement foundation, with proper bolt holes, and sometimes have to spend a good deal of time explaining the necessity for it. Even then our instructions are frequently not carried out, and the result is a break-down, a bill for repairs and a vigorous kick against the machine.

"Only a short time ago we sold a big compressor to a company and furnished blue prints so that the bolt holes could be left in the proper places in the foundation. After we had shipped the machine we received a bill for damages because the holes in the frame did not fit those in the foundation. They had left the holes in the foundation too small, and, instead of having to set the bolts with fresh cement, had to enlarge the holes, and they wanted us to pay for their mistake.

"A friend of mine, in visiting a prominent mine in a certain district, as soon as he entered the shaft house, noticed a peculiar pounding that told him something was out of order. He at once started to locate the trouble, and in a few minutes found it in the compressor. The engineer sat at the big hoist, perfectly unconcerned, and the visitors continued their investigations to definitely locate the difficulty. The dial plate on the air receiver showed that the compressor was making air all right, the indicator marking ninety pounds pressure. But while they looked, the air drills in the workings were started and the pressure at once went down to twenty pounds. Some time after their visit a new management took hold of the property and at once proceeded to make necessary repairs. They found that one side of the compressor foundation was more than half an inch lower than the other, causing the air cylinders to leak, and that the drills and connecting pipe were out of order, thus accounting for the loss of air. It cost several days' work to put the machinery in shape.

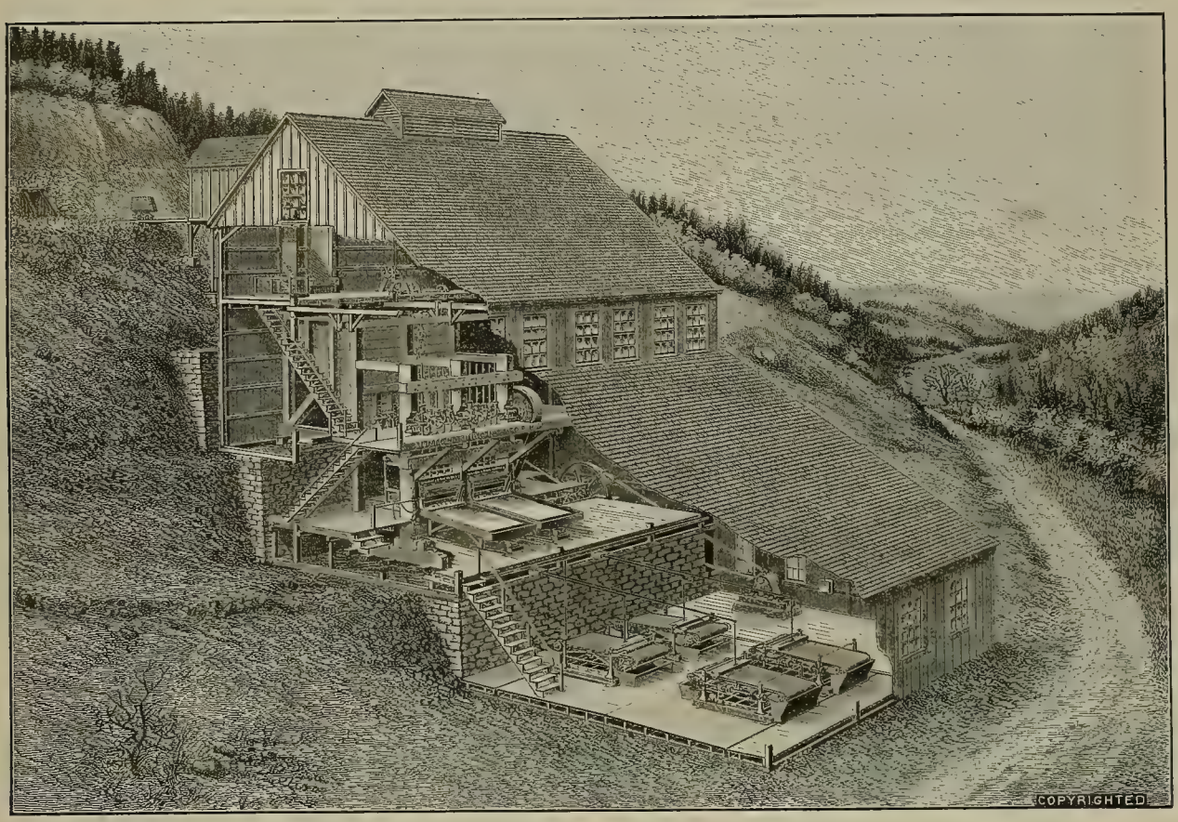
"One potent reason for so much trouble with mining machinery is the fact that so many mining engineers imagine because they are thoroughly conversant with the opening and operation of mines that they know all about machinery. Many of the best engineers in the country, when submitting specifications, are so rigorous in their requirements as to prices and methods that the machinery houses are placed at a disadvantage and the way is left open for reckless dealers to introduce inferior machines. No end of trouble arises from this fact. Competition has reduced prices to a close margin, and when a sale is made below these margins, it may be relied upon that the loss is made up in some way, either by shaving the weight or by defective or coarse workmanship.

"One of the heaviest purchasers of mining machinery in Colorado never attempts to cut down prices below a reasonable margin. He is thoroughly posted regarding the character of the different machines in use and their prices, and it is impossible to impose upon him, but he knows just what he wants and pays a fair price without grumbling. The consequence is that he pays less for repairs in proportion to the number of men employed than any other large enterprise in the State. There is no other business in the State in which it is more important to have the best machinery and to give it the best care."—Denver Republican.

A Natural Motive Force.

An Arizona miner has suggested the feasibility of running mining and milling machinery by means of windmills. He says:

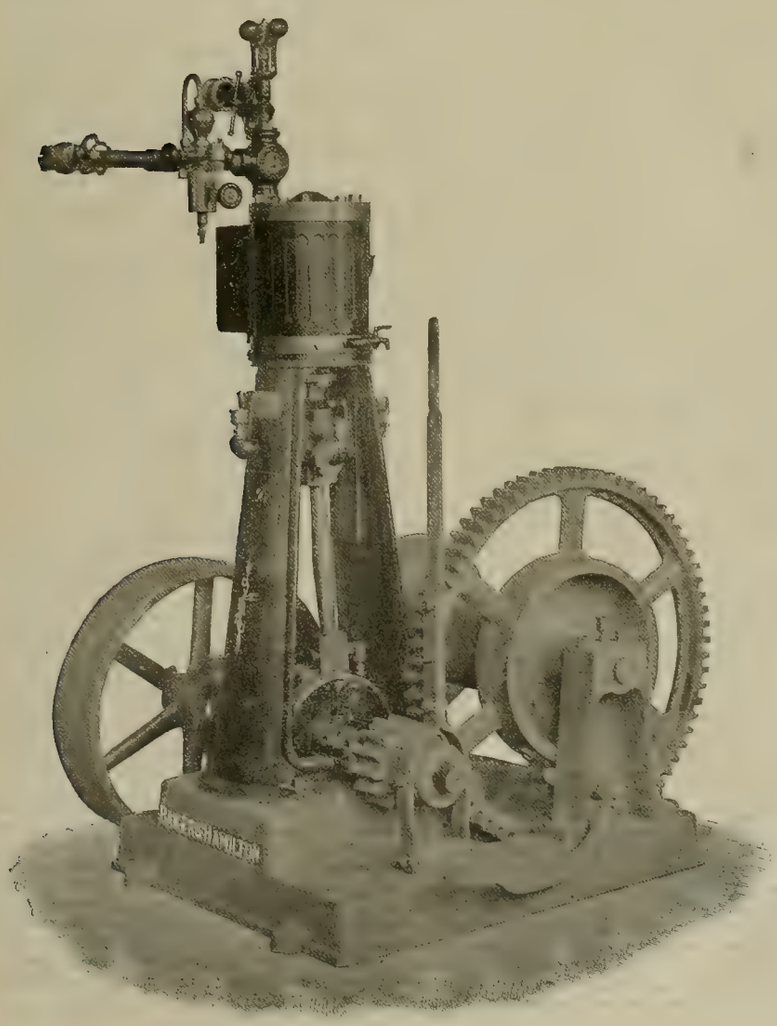
Arrastras and stamp batteries can be run with windmills. Fuel is expensive in many places, and a high velocity of wind prevails about three-fourths of the time. A 16-foot power mill will run a 2 stamp battery, 600-lb. stamps, and pump the water. A good practical plant for the prospector is a 5 stamp battery, with stamps of 600 pounds each, amalgamating plates, battery feeder, a 6-foot concentrator, a water tank, force pump and pipes of proper size. The pump can be placed in a well 500 feet distant from the mill, if desired, and a rope run from the windmill to the pump to drive it. A 20-foot windmill erected on a strong wood tower, the shafting can be placed in the tower and the battery set about 12 or 15 feet distant. Any kind of a roof or shade that will keep out the sun and rain will do. With such a mill, ore can be worked by the free gold amalgamating and concentrating process at an expense not exceeding $1 per ton. In our mining district there are thousands of tons of ore and waste on old abandoned claims, a large percentage of which will yield by this process from $3 to $9 per ton and upwards. Erect windmills and small batteries and work these old dumps. They are nearly all free-gold ore, and a concentrator will not be necessary.



A Substitute for Platinum.

Seeing the growth of the electric lighting industry and the advance that has taken place in the price of platinum, the demand for some reliable substitute for the latter is becoming more urgent. Its value in connection with incandescent lamps, etc., is due to the fact that its co-efficient of expansion is identical with that of glass. Consequently, when an incandescent lamp becomes heated, both the glass and platinum expand equally and simultaneously, obviating any risk of the glass breakage or of the separation of the materials. It is now claimed that M. C. E. Guillaume of Switzerland and M. L. C. Dumas, a Frenchman, have discovered that an alloy of nickel and steel can be obtained to take the place of platinum in this connection. By varying the proportions of either metal an alloy results with almost any desired co-efficient. When only a small proportion of nickel is employed, a co-efficient of expansion between that of iron and that of nickel is obtained. With 23% of nickel the co-efficient of expansion of brass is reached. As the proportion of nickel is then increased, the co-efficient of expansion progresses until, when the nickel reaches 37%, it becomes practically nil. Beyond that an increase again takes place until, with 45% of nickel in the alloy, the co-efficient becomes equal to that of platinum, and the result becomes of importance to the electrical industry.—Industries and Iron.

KRENNERITE, a telluride of gold and silver, uncommon in the United States, is found in the Independence mine, at Cripple Creek, Colo. It occurs in brilliant crystals of a pale yellowish-bronze color, tin-white on cleavage faces. Eliminating the insoluble matter, an analysis shows the mineral to contain 43.86% gold, 0.46% silver and 55.86% tellurium. The crystals are small and about as broad as long, and the prismatic faces are striated. They have a perfect basal cleavage, which is a prominent feature of the mineral. The lack of any appreciable quantity of silver in the Cripple Creek ores, as shown by the returns of the smelters, is proof that much, if not nearly all, of the mineral passing as sylvanite is either krennerite or its sub-species, calaverite. Krennerite ranges from silver-white to brass-yellow in color, and is so near sylvanite in its physical properties that frequently the eye cannot distinguish one from the other.—Georgetown Courier.

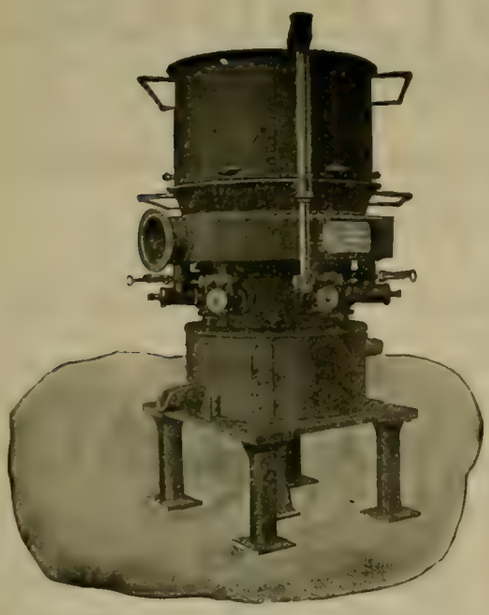


UNION IRON WORKS,

222 Market Street, San Francisco, Cal.

The above is an illustration of a First-Class Modern 10-Stamp Gold Mill.
For particulars, send for Catalogues.

Builders of All Classes of Mining Machinery.



Klondike Hoist.

Single Cylinder, Vertical, Friction Drum, Portable Hoist. With Fixtures Complete. Specially adapted for the use of Klondike Miners, as Overhung Pulley makes it possible to use Hoisting Engine for driving Pump or Saw at the same time that Engine is hoisting. The light weight that it is possible to knock down Hoist for shipment is attractive to users at points where it is necessary to sleigh or transport by mule back.

BAKER & HAMILTON,

SAN FRANCISCO, SACRAMENTO, LOS ANGELES, NEW YORK.

BOILERS, ENGINES, STEAM HOISTERS, ELECTRIC HOISTERS, ROLLS, CRUSHERS, WILFLEY TABLES, CARS, CAGES, ORE BUCKETS, RAIL, PIPE, FITTINGS, BELTING, ETC., ETC.

THE : CAMMETT : CONCENTRATOR.

Designed with some Regard for the Laws of Concentration.

The perfect vanner motion given to the pulp by our head motion, together with the freedom from "jumping" resulting from the special rigid guides used, explains why the Cammett riffles never "pack," and why the table has such a great capacity when handling slimes.

The continuous grooves and riffles extending from end to end of the table maintains the greatest possible margin of safety between the concentrates discharge and the tailings.

Thoroughly Protected by Strong Patents. Write for Circular.

Fraser & Chalmers are General Agents for the Green Blowers.

THEY MAKE

STAMP MILLS, CRUSHERS, VANNERS, SMELTING FURNACES, HUNTINGTON MILLS, ETC.

THE BRYAN ROLLER QUARTZ MILL.

We are the sole manufacturers of this Mill. A test made by the Bullion-Beck Co. of Eureka, Utah, with this and the Huntington Mill proved conclusively every claim we made for the Bryan Mill, viz: that the Bryan would crush more ore with less repairs, less power and less slimes than any Mill made. Result—they are now operating three of the five-foot Bryan Mills and find them superior and more satisfactory than any Mill they ever used. L. C. Trent & Co., who had formerly sold the Huntington Mill, immediately manufactured a Mill infringing our patent. Suit brought in the U. S. Court resulted in a verdict in our favor, and we shall prosecute to the full extent of the law any infringement of any character whatsoever in the MAKING, USING or SELLING of the same. : : : : : : : : : : :

Strong.
Economical.
Simple.

MANUFACTURED BY

The BRYAN MILL is constructed on the principle of the Chili Mill, except it has three rollers arranged to run in a continuous discharging pan. It crushes either gold or silver ores. It consists of an annular cast-iron mortar with fixed steel dies arranged in the path of its three crushing rollers. Power is applied direct from a pulley through a bevel gear and pinion secured to stationary center post. We present a few of many advantages it possesses over any other Mill: Larger screen capacity and free discharge. Amalgamates a larger percentage of gold. Quickly and cheaply erected; with regular feed and proper flow of water requires little attention. Crushes hard or soft ore with smaller amount of power per ton and less wear and tear of machinery. : : : :

PATENT SOLICITORS,

330 MARKET STREET, - SAN FRANCISCO, CAL.

Inventors on the Pacific Coast will find it greatly to their advantage to consult this old experienced first-class agency. We have able and trustworthy associates and agents in Washington and the capital cities of the principal nations of the world. In connection with our scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of patents already granted, for the purpose of determining the patentability of inventions brought before us, enables us to give advice which will save inventors the expense of applying for patents upon inventions which are not new. Circulars and advice sent free on receipt of postage. Address **DEWEY, STRONG & CO., Patent Agents, 330 Market St., San Francisco, Cal.**

"The Proof of the Pudding is in the Eating."

Something over a year ago, two of these Richards' Patent Triple Plunger Pumps, with motors as shown, were supplied to a mine in Mexico, for the purpose of raising water to an elevation of 650 feet. The owners were so well pleased, that they ordered another of the same a few months later. These pumps were arranged with outside packed plungers, for pumping muddy water — designed for that purpose, they did it satisfactorily.

For all purposes where a uniform resistance to the driving motor is a consideration, these pumps are admirably adapted. Triple Plungers and crank shafts run in a bath of oil if desired. Made with large valve areas, and by actual test develop a very high efficiency. Furnished with or without motors, or for use with gas or steam engine.

This is only one of over fifty different kinds of pumps we make.
Our 1899 Catalogue tells all about them; sent on application.

SPADONE'S CONCENTRATOR BELTS.

PATENTED.

This illustration shows the edge flanging outwardly as it passes over the pulley. This relieves the strain from the top and bottom of the edge by directing the strain automatically to the inside face surface of the edges. Heretofore all belts have been so constructed that when they pass over the pulleys or rolls, a direct strain comes upon the top or at the base of the edges, causing the edges to break away from the body of the belts in a very short time. *We avoid this Mechanical Defect by our Spadone Curved Edge.* Belts made to fit any machine—4, 5 and 6 feet wide. Prices and samples on application.

AMALGAM PLATE CLEANERS.

Our Amalgam Plate Cleaners are made of Pure Rubber in moulds, thus insuring a plate cleaner which will not scratch the plates and a perfect edge which will clean the Amalgam plates evenly. They are made 6 inches long, 3 inches wide and ⅛ inch thick, making a convenient size to handle. Price by mail to any address, each 75 cents. Correspondence solicited.

Send us your order for Water, Air Drill, Steam, Suction and Fire HOSE, RUBBER BELTING, RUBBER PACKING and LEATHER BELTING.

Market Reports.

SAN FRANCISCO, Sept. 7, 1899.

SILVER.—London, 27 5-16d; New York, 59¼; San Francisco, 59½; Mexican Dollars, 48@48¾; New York exchange, sight, 10; telegraphic, 12½ cents premium.

LEAD.—New York reports quiet, $4.60 bid, $4.62½ asked; brokers' price, $4.40. Local, pipe, 7¼@7½c; sheet, 7¼@8¼c; pig, 6¾c; bar, 6½c.

COPPER.—New York reports Lake unchanged at $18.50; brokers' price, $18.50. Local—Mill copper plates, 23¼c.

There is practically no change in copper within the week. The anticipated higher prices do not obtain. The continued successful substitution of aluminum for copper in electrical equipment is having an effect, evidently, as it is now seen that a substitute for copper has been found.

IRON.—American, soft, $22.50@24.50 per ton; Scotch, $27.50 Local bar, 2¾c per lb.

STEEL.—11¼@20c per pound.

TIN.—Firm for spot and easy for futures; $32 bid; $32 25 asked; pig, 36@39c per lb.

The world's visible supply of pig tin Sept. 1 was 1255 tons less than Aug. 1. Decrease in visible supply at London was officially given at 703 tons, but other sources of information make decrease 1015 tons. Stock in United States of pig tin on Sept. 1, exclusive of Pacific coast, as stated by Metal Exchange, is 2298 tons. This is believed to be an overestimate. Reliable estimate of United States stock is less than 1000 tons. Production of tin is not increased, while consumption is growing. Decrease in stocks will, it is believed, cause higher prices.

ANTIMONY.—In San Francisco 1000 pounds and upwards, 10c net; 300 to 500 pounds, 11@14c; less than 100 pounds, 15c.

BABBITT METAL.—No. 3, 8¾c.

QUICKSILVER.—Demand strong and active. Local, $45.50; export, $40.50@41; carload lots, special rates.

The foreign demand for quicksilver and a light supply are forcing the price upward. A number of old mines have recently been reopened in California and new ones are heard of, but the demand is fully up to the supply. W. B. Buckminster says of the quicksilver properties under his management: "The price of quicksilver has advanced $1.50 per flask in the last ten days and the stock is the smallest I have ever known. I cannot see how stocks are going to be increased, notwithstanding the fact that our mines control the output in this country. I look to see quicksilver sell at $50 a flask, but I do not want the price to advance to a point where every prospector would be scraping the ground, looking for quicksilver properties, as has been the case in copper by reason of the large advance in that metal."

PLATINUM.—London, 63½s per ounce; York, $16.25; San Francisco, $16.75.

ALUMINUM.—No. 1, 99% pure in ingots, for remelting, 37c per pound, in small lots; 35c per pound in 100-pound lots; 33c per pound in ton lots and over. No. 2 grade, 90% pure, cast in ingots for remelting, 34c per pound in small lots; 33c per pound in 100-pound lots; 31c per pound in ton lots and over. Aluminum castings, according to number, weight, moldings, etc., 45c per pound, upward. Aluminum sheet from 38c per pound upward. Lots of less than 50 pounds, 5c per pound higher. Nickel aluminum casting metal, 39c per pound in small quantities; 35c in 100-pound lots and 33c in ton lots.

ASSAY LITHARGE.—100 lbs., 12c.

POWDER.—F. o. b. San Francisco: No. 1. 70% nitro-glycerine, per lb., in carload lots, 15¼c; less than one ton, 17¼c. No. 1*, 60%, carload lots, 13½c; less than one ton, 15¼c, No. 1** 50%, carload lots, 11¾c; less than one ton, 13¾c. No. 2, 40%, carload lots, 10c; less than one ton, 12c. No. 2* 35%, carload lots, 9½c; less than one ton, 11½c. No. 2** 30%, carload lots, 9c; less than one ton, 11c. Black blasting powder in carload lots, minimum car 728 kegs, $1.50 per keg; less car lots, $2 per keg.

FUSE.—Triple tape, $5.10 per 1000 feet; double tape, $4.85; single tape, $3.45; Hemp, $3; Cement No. 2, $4.35; Cement No. 1, $3.45.

CAPS.—3x, $5.50 per 1000; 4x, $6.50; 5x, $8; Lion, $9.

CHEMICALS.—Cyanide of potassium, jobbing, 32@33c per lb.; carloads, 29@30c; in 10-lb. tins 37c; sulphuric acid, 1¾c per lb. 66° B.; soda ash, $1.60 per 100 lbs. 58%; hyposulphite of soda, 2½@2¾c per lb.; blue vitriol, 5½@6c per lb.; borax, concentrated, 7@8c per lb.; chlorate of potash, 12@13c; roll sulphur, 6c; alum, $1.90@2.00; flour sulphur, French, 2¾@2¼c; California refined, 1½@1¾c; nitric acid, in carboys 8c per lb; caustic soda, in drusm, 3@4c per lb.; Cal. s. soda, bbls., 65c; sks., 60c per 100 lbs; chloride of lime, spot, 2.10@2.25c; nitrate of potash, in kegs, 8c; chlorate of potash, 25c; caustic potash, 10c in 40-lb. tins.

OILS.—California Castor, pure, cs., $1.10 per gal.; bbl., $1.05; pure No. 2, cs., 85c; bbl., 80c; Baker's AA Castor Oil, in case lots of 200 gals. and upward, $1.15; less than 200 gals., $1.10; in bbls., 4c per gal. less than case; Baker's Crystal, $1.40; China Nut, 50c; Linseed, strictly pure, boiled, bbl., 50c; cs., 55c; raw, bbl., 48c; cs., 53c; lots of 5 bbls., 1c less; Lucol, boiled, bbl., 44c; cs., 49c; raw, bbl., 42c; cs., 52c; lots of 5 bbls., 1c less. Kerosene—Pearl, cs., per gal., 16½c; Astral, 16½c; Star, 16½c; Eocene, 18½c; Extra Star, 20½c; Elaine, 21½c; Water White, bulk, in tanks, 11½c; Mineral Seal, iron bbls., 21c; wooden bbls., 23½c; cs., 26c; Mineral Sperm, 27c; Deodorized Stove Gasoline, bulk, 16c; do., cs., 21c; 86 deg. Gasoline, bulk, 21c; do., cs., 26c; 63 deg. THE BROWNELL "PATENT LIP" FLANGE FRUE VANNER BELTS.

It has taken years of ceaseless testing and experimenting to produce the superior belt which we now offer, with elastic flanges and pliable body reinforced with specially woven duck. Every belt is manufactured by experienced workmen, and carefully tested on machines especially built for that purpose; consequently we are to-day manufacturing the best belts that mechanical ingenuity, combined with honesty of construction, can possibly produce.

SUPT. OFFICE WILDMAN GOLD MINING COMPANY,
SUTTER CREEK, AMADOR CO., CAL., Feb. 22, 1897.

MR. JAS. S. BROWNELL, 132 Market St., San Francisco, Cal.—DEAR SIR: Replying to your favor of the 18th inst., will say that in the two mills operated by this company we have nineteen of your Patent Lip flange concentrator belts in use; some of them have been in constant use for the past two years and have given entire satisfaction. I know of no better flange for a side shake machine.

Yours truly, JOHN ROSS JR., Superintdenent.

MEXICAN MILL. EMPIRE, NEV., March 28, 1897.

MR. J. S. BROWNELL, San Francisco, Cal.—DEAR SIR: For some years we have used three different styles of belts on our Frue vanner at the Mexican mill, and for smooth working and endurance the Brownell Patent Lip flange belt has proved its superiority over all others, and I unhesitatingly recommend it to all who are using Frue machines.

Yours truly, EUGENE MAY, Foreman.

ROPP STRAIGHT LINE FURNACE

FOR ROASTING, CHLORINATING AND DESULPHURIZING ORES.

Extracts from Letters Received from Mr. Philip Argall, Manager the Metallic Extraction Co., Cyanide, Colorado:

January 2, 1897.

"The roasting is invariably good. We can do 80 tons per day to 0.13% sulphur, when everything runs smooth. Our month record which, of course, includes all delays, is 1700 tons, from 1.94% sulphur to 0.16%."

February 19, 1897.

"Our furnace is now running very nicely indeed, averaging 90 tons per day to 0.10% sulphur, and doing excellent work; in fact, it has improved right along and we are highly pleased with it.

"For 24 hours ending 7 A. M. to-day 102 tons were roasted."

The **ROPP FURNACE** is now in successful operation at the following reduction works: The Hanauer Smelting Works, Salt Lake City, Utah (one furnace); The Metallic Extraction Co., Cyanide, Colo. (one furnace); The Colorado-Philadelphia Reduction Co., Colorado City, Colo. (three furnaces); The Selby Smelting & Lead Co., Selby, Cal. (two furnaces); The Mount Morgan Gold Mining Co., Rockhampton, Queensland (one furnace); Broken Hill Proprietary Co., Broken Hill, New South Wales (four furnaces); Puget Sound Reduction Co., Everett, Washington; Colorado Ore Sampling & Reduction Co., Cripple Creek, Colo.; Consolidated Kansas City Smelting & Refining Co., for the Arkansas Valley Smelting Works, Leadville, Colo.; Robert Lanyon's Son's Spelter Co., Iola, Kansas (two furnaces); Mountain Copper Co., Ltd., Keswick, Cal.

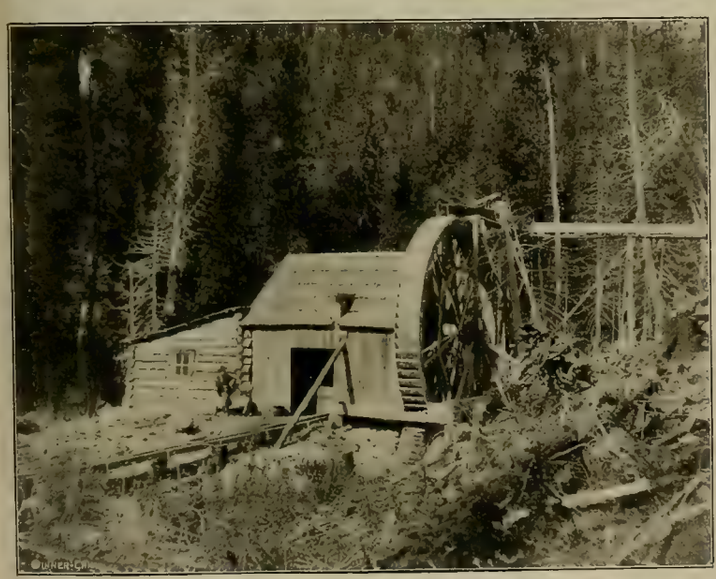
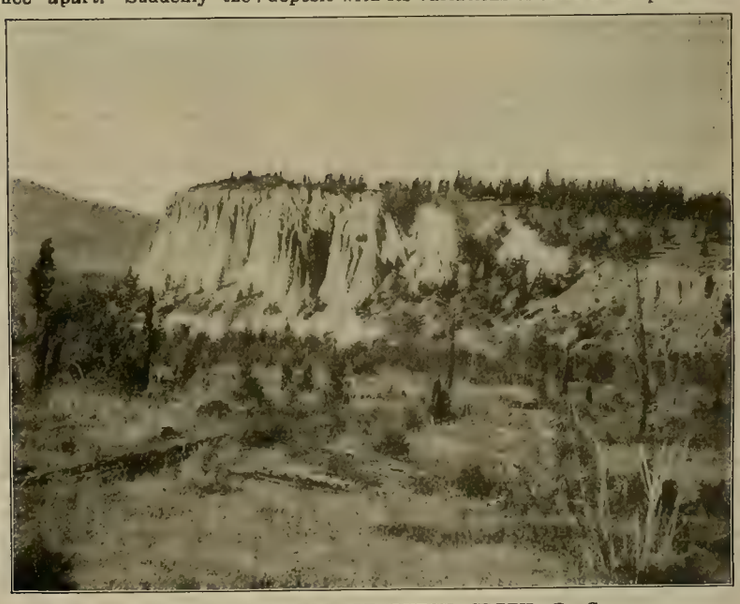
Scenery of British Columbia.

The picturesqueness of the scenery in British Columbia is illustrated in the accompanying engravings. Most of the smaller streams rise in the higher mountain ranges, being supplied by the heavy fall of snow in winter, and during summer by numerous never-failing springs. The streams have cut their sinuous ways deep into the rocky strata and these gorges and canyons constitute a most attractive feature of that province. Bull river was the scene of a placer excitement in the early sixties, when the discovery of rich diggings a mile above and below the Old Pack bridge, made the stream famous and a number of moderate fortunes were realized. Bull river is at all times a good-sized stream, swift and broad until it enters the canyon, where it is confined to a width of about 30 feet by perpendicular walls of quartzite. Through this gorge the river drops nearly 300 feet in a succession of falls and rapids in the distance of a mile. The stream rushes along, lashed into foam where sharp-angled turns obstruct its passage. Near the bridge it leaps over a precipice 80 feet in height, forming a beautiful cataract which sends up a cloud of mist in which is hung a beautiful rainbow on each clear day. Below the bridge the canyon deepens until its abrupt walls are 200 feet high, though scarcely half that distance apart. Suddenly the canyon widens into a charming valley surrounded with gently sloping hills densely timber clad. The Bull River canyon is considered one of the most beautiful bits of scenic grandeur in British Columbia.



SAND CREEK, S. E. KOOTENAY, B. C.



BULL RIVER CANYON, S. E. KOOTENAY, B. C.

Sand creek is also a picturesque stream, cutting its way down through twisted and contorted metamorphic rocks. The illustration shows it to be quite as wild and rugged as the canyon of Bull river. Along the former streams are numerous promising mineral locations, in which sulphide ores occur carrying copper and silver. Another type of scenery, wholly different from the deep, narrow gorges above described, is found at the mouth of Dutch creek, where recent erosion has cut deep into the alluvial banks, leaving that strange type of earth sculpture familiar to the hydraulic miner, who in a few months or days imitates the work of nature which has required centuries, and changes a smooth, sloping hillside to an abrupt, precipitous bank in which the character of the stratified deposit with its variations of color are exposed. The Dardanelles claim is on Wild Horse creek, ten miles from Fort Steele. The tunnel is 2200 feet above the creek. Ore has been hauled on a "go-devil" to the arrastra illustrated on this page.

DARDANELLES ARRASTRA, WILD HORSE CREEK, B. C.

CUT BANK, MOUTH OF DUTCH CREEK, B. C.

MINING AND SCIENTIFIC PRESS.

ESTABLISHED 1860.

Largest Circulation of any Mining Journal on the American Continent.

Office, No. 330 Market Street, San Francisco, Cal.
Telephone Number, Davis 771.

ANNUAL SUBSCRIPTION:
United States, Mexico and Canada.....$3 00
All Other Countries in the Postal Union.....4 00

Entered at the S. F. Postoffice as second-class mail matter.

J. F. HALLORAN.....Publisher

San Francisco, September 16, 1899.

TABLE OF CONTENTS.

ILLUSTRATIONS.—Sand Creek, S. E. Kootenay, B. C.; Dardanelles Arrastra, Wild Horse Creek, B. C.; Bull River Canyon, S. E. Kootenay, B. C.; Cut Bank, Mouth of Dutch Creek, B. C., 309. General View of Congress, Arizona, 312. At the 1850 Level, Congress, Arizona, Mine; Bottom of Shaft at 1750 Feet, Congress, Arizona, Mine, 313. The Folsom, Cal., Sawmill—First One in the World Run Wholly by Electricity; Another View of the Sawmill at Folsom, Cal., Run Wholly by Electricity supplied by the Folsom-Sacramento Electric Transmission Plant, 316. Topics for Coal Miners, 317.

EDITORIAL.—Scenery of British Columbia, 309. The Leasing System; The Limitations of Liquid Air; The Selection of a Mill Site; Miscellaneous, 310.

MINING SUMMARY.—319-320-321.

THE MARKETS.—The Local Markets; Mining Share Market; Sales in San Francisco Stock Board, 324.

MISCELLANEOUS.—Concentrates, 311. Republic District, Washington; The Congress Mine, 312. Metamorphism of Rocks, 313. Rand Deep Levels; Volume and Head of Water, 314. Latest Mining and Metallurgical Patents, 315. Folsom-Sacramento, Cal., Transmission Plant, 316. Telegraphing Without Wires; Topics for Coal Miners; Observations on Rock Drilling; Double-Barreled Tunnel; Largest Steel Shaft, 317 Prominent Achievements in Metallurgy; Electrolytic Separation of Cadmium From Iron; Output of Iron Mines; A Delicate Instrument; The Assay of Foreign Lead Ore; An Old Wagon Bridge; The Oldest Iron Steamship; Rare Brazilian Sand Used for Incandescent Mantels; Thirty-three Miles of Aluminum Cable; Underground Working of Leadville, Colo., Mines, 318. Industrial Notes; Personal; Recently Declared Mining Dividends; Commercial Paragraphs; List of U. S. Patents for Pacific Coast Inventors; Notices of Recent Patents; Books Received; Obituary, 321-22.

COLORADO county officials assist the mining industry in that State by constructing roads into isolated districts at public expense. The mine owners derive a direct benefit from this enterprise, of course, but the public benefit is not so far removed as to be undiscernable.

ANOTHER attempt is to be made to work placer mines in Arizona adjacent to the Colorado river by pumping water from the river. It is expected that the engineering features will be handled with more effectiveness than that which characterized a similar installation at Picacho a few years ago.

FAILURE to recognize the important and well-established fact that all veins have pay shoots and relatively barren portions has more than once resulted in failure. All pay shoots do not reach the surface, but the greater number of them do. When developing a vein the pay shoot should be sought and explored.

GOOD, developed and going mining properties are in demand everywhere, but the call for undeveloped and unpromising prospects, and mines having large development and equipment which no one has yet succeeded in making a paying proposition, are slow of sale. A few mines are offered at a cost below their probable value, but the reverse is usually the case.

PROSPECTORS are about to make another effort to discover the "Pegleg" Smith mine, supposed to be somewhere in San Diego Co., Cal. Several men have already lost their lives in the fruitless search for this ignus fatuus, and now others no less foolhardy are about to attempt it. The "Pegleg" story has been printed and told for years, and there is little doubt that it originated in a newspaper office, and has no foundation in fact.

A GLASS manufacturer at Anderson, Indiana, illustrates what keen observance and constructive intellect can do. Passing recently through his factory he saw a glass globe on an electric arc light crack, a small chip fall therefrom on the carbon, and almost immediately a drop of liquid glass fall to the floor. He at once built a vat with sides and bottom made of carbons, over which could be turned lateral and longitudinal currents, ran the sand through, and, according to an Indiana paper, "the molten glass is being turned out in as many seconds as it required hours for the old fuel to make it."

The Leasing System.

Much can be said in favor of the leasing system in mines where the veins are comparatively small and the values spotted. Time and again leasers have taken properties abandoned by corporations as failures and have made them pay from the commencement of operations, by the leasing system. The natural inference is that there must be some good reason for this, and there is. There are, in fact, several reasons. In the first place, the leaser is working for himself, and that is an incentive to greater effort. The more rock he can get out on a shift the cheaper his mining cost. He works faithfully. Usually he has one or more partners, and if there be a laggard among them, he is spurred on to greater endeavor; but usually the probability of increased gain is sufficient to keep him at work. The mine manager cannot understand this and says: "These men should work just as hard for us as for themselves." But the men will not do it. They will give an honest day's work; but there is no incentive, no premium, if they accomplish more than a day's task; so the miner satisfies himself with eight or ten hours' work, and the management must also be satisfied.

The leaser has little capital invested, and so is not losing interest on plant, nor suffering from its deterioration. He sells his product to the highest bidder, and he gets "all there is in it," less his royalty, which is fixed by agreement at an arbitrary percentage on a sliding scale based upon the changing value of the ore.

The leasers are their own managers and their own clerical force, and these and many other expenses which cut into the profits of a corporation are dispensed with. They pay no insurance, no taxes, and sustain no "city office."

They reduce the proposition to the plane where it naturally belongs: that of legitimate mining stripped of unnecessary expense. Their share of the expenses of deterioration, taxes, etc., are all covered by the royalty percentage, determined before they commence work. If they make nothing, they lose nothing but their time and the actual expense of supplies consumed. Of course, this contemplates the small parties of individual leasers, who take the whole or a part of a mine on tribute. Some mines are operated under lease with all the circumstance which attends a corporate enterprise; but usually the management of leases so operating look very closely to the results accomplished, more so, perhaps, than the managers of corporations.

In Colorado the leasing system is very popular and contributes a large proportion of the output of the State.

The Limitations of Liquid Air.

During recent years some wonderful discoveries have been made—the X-ray is one of the most recent and it is already being successfully applied in many useful ways. The telegraph and telephone no longer seem wonders because of daily familiarity, and so in time the X-ray will become as commonplace as the telephone. The latest discovery is the process of making liquid air. The enthusiasts say wonderful things are to be accomplished by the use of liquid air, and no doubt this is so. The substance is in tself wonderful enough to astonish the most learned, but when it is said that liquid air will be manufactured for almost nothing from the air surrounding us in such abundance and which is free to all alike, and that in the liquid form it will generate a power far in excess of that required to manufacture it, there arises a doubt in the cautious mind. "Look at the telegraph, the telephone and the X-ray," says the enthusiast. "Are liquid air and its possibilities any more improbable than the application of electric forces was considered before they became so well known?" The telegraph, telephone, X-ray, electric transmission of power and similar devices are each in direct accord with nature and not contrary to its fundamental principles, as are the claims for the generation of increasing power from liquid air. The transmission of power by electricity is now a familiar thing, but it is a well-recognized fact that it is with a constant loss from the point of generation, whether by steam or water power. There is loss in the generator, loss in the transmitting line, loss in the motor and loss in the machines to which power is directed. So with steam, with water power and every other motive force. Is it then likely that liquid air will controvert nature and accomplish that which no other force known can attain? It is not probable. The only accelerating force with which all are familiar is gravity and this must not be trammelled by the devices of men or it too loses its power by reason of frictional resistance.

The Selection of a Mill Site.

When determining upon the location of a mill or other machinery for the beneficiation of ore, the surroundings should be studied in reference to the economy of transportation and treatment. The mill should be placed where the ore can be delivered from the mine into its highest portion, above the bins, without the necessity of hauling the ore up an incline as is often seen, and that, too, where it could have been avoided. The mill should be furnished with every mechanical device which will reduce the expense of manipulation to a minimum, the ore passing from one process to another by gravity. Water is an important consideration and the mill must have a liberal supply. Often it is a question of choice between locating the mill near the water and at a distance from the mine or placing the mill near the mine and pumping water to it from a lower elevation. When this problem presents itself, it becomes a question of economy—which will be least expensive, to tram the ore to the mill at the water or pump the water to the mill. The selection of site is also influenced by the topography of the ground. If a good site is obtainable at the mine and it would be necessary to pump water up to the mill, even if the latter were located near the water, it will in most cases be wise to build the mill at the mine and pump the water unless the distance and elevation be prohibitive. Experience has already demonstrated that large volumes of water may be pumped many miles against 500 feet or more head at nominal expense per ton of ore treated if the quantity be large—200 tons or more daily. No two situations are identical and these matters are wholly dependent upon the judgment of the management. The economical features must be considered, the relative cost determining the proper course to pursue.

A RECENT apparently authentic cablegram from South Africa was to the effect that the Transvaal Government had declared that in the event of war with England the Boers would wreak ruin on the mining interests there by blowing up the mills, and wreck the works generally. This savage threat did much to alienate sympathy from their cause, as such a course would be barbarous reprisal directed against innocent investors. This week comes a statement from the Witwatersraud that the Transvaal Government desires to keep the mining industry going, and wants to protect it; that it has notified the Rand companies that their men will receive protection as long as they remain peaceful, and should war unfortunately occur, the men will be given a reasonable time to leave the country if they desire, which sounds more civilized. However great the provocation on both sides, it is manifest that cooler counsels will prevail, and that armed collision will be at least deferred.

DIVIDENDS are essential to success in a mining enterprise under corporate as well as private management. Most mining companies find that it requires time and the expenditure of considerable sums of money before the dividend period is reached; but occasionally an exception is found, and dividends are advertised before the machinery is actually in operation. The Little Tiger Mining Co. of Boston, Mass., a new enterprise, operating near Yreka, Siskiyou Co., Cal., started up its mill last week, but shut down to make some necessary repairs. The company has, however, already announced a dividend.

AMONG trade values "good will" is a recognized quantity. So, also, is an old established street number, a firm name, and occasionally come new elements deemed valuable, as in the recent instance of a Kansas City, Mo., firm, which, consolidating with another concern in the same business, retains its old telephone number, which it values at $3000.

Concentrates.

IT is expected that coinage will begin at the Denver mint early in 1900.

TO ANNEAL STEEL make it hot, put in hot ashes or charcoal dust and cool slowly.

METALLOGRAPHY has been defined as "the science of metals, with special reference to their structure."

THE law makes no mention of a strip of land of definite width on either side of a ditch, flume or pipe line.

A SCIENTIFIC, illustrated explanation of the international date line, all about it, appeared in the issue of Dec. 3, '98.

A CONTRACT that a single person shall be employed as the sole agent of manufacturers to sell their output is valid and enforceable.

UNDER the "permit" system no competent miner should have present difficulty in securing work at Wallace or Wardner, Idaho.

THE value and economy of superheated steam has long since been recognized, but still is not in general use, owing to practical difficulties.

TWO YEARS' assessment may be done on claims at one time by performing half the work in December and the remaining $100 worth in January.

THE yield from the Klondike region has thus far reached about $11,000,000 this year, and it is estimated that it will reach $18,000,000 for the season.

MAGNESITE usually occurs with serpentine and other magnesian rocks. It is chalky white to cream color, and may be either hard or soft; often earthy.

PEARLITE is a volcanic glass, in which a peculiar structure has resulted upon the cooling of the magma. It is light gray in color and has a pearly luster.

THE demand for aluminum has made the mining of bauxite, which is an ore of aluminum, a very profitable business in some localities where these deposits occur.

CONCENTRATION is almost as ancient as mining. The separation of gold from alluvial soil was effected in Brazil a century ago by placing rawhides in sluices, the hair side up.

BURN no more candles or lamps under ground than necessary where ventilation is poor. Each candle consumes more oxygen than a man and only decreases the scanty air supply.

SOMETHING new in strikes is reported from the Helena-Frisco mine, Idaho, where the entire day shift walked out, refusing to go to work unless three union miners were discharged.

THE New York man who asks for advice regarding investment in Copper King of Arizona stock might hear something to his advantage by addressing Gov. Murphy of that Territory.

COLORADO and Utah have the largest published lists of dividend-paying mines. Many of the California producers are of private ownership and make no announcement of their affairs.

THE exports of the United States now reach $1,000,000 per day, against half a million daily five years ago. Among the exports, mining machinery and supplies form a prominent item.

THE largest stamp mill in Canada is in the Salmon River district, on the property of the Montreal Co. It has sixty stamps. There is a 40-stamp mill on the Richardson mine, in Stormont district.

WASHINGTON State miners propose this season to take advantage of their new mining law by putting a portion of their assessment work on the roads and trails leading to their mines where necessary.

A STATEMENT of account sent in lieu of a draft to a bank or other collecting agency for the purpose of collection is subject to taxation as an order for payment of money and requires a two-cent revenue stamp.

GRANITE-PORPHYRY is a granite rock of normal type in which have developed distinct crystals of some mineral, larger than those composing the make-up of the rock. These crystals are usually feldspar.

THE Golden City mine, in Stanislaus county, Cal., was worked years ago and was anomolous in some respects. The gangue was chiefly heavy spar, and required unusual care in timbering. It was rich in gold.

GRAPHIC granite is usually found in dykes of coarsely crystallized granite called pegmatite. It is a mixture of quartz and feldspar in which the arrangement resembles the characters used in ancient writings, hence the name.

EIGHTY-FOUR per cent of the entire State of Idaho is still public land, amounting to more than 44,000,000 acres. Of this area it has been estimated by the Government Geological Survey that 7,000,000 acres can be successfully irrigated.

PARTS II and III of "Aaron's Assaying," the standard work on that subject, revised and newly issued, being the third edition of that popular work, is out to-day. It is reduced in price and increased in excellence, and is recommended.

ALLOYS are of three kinds: those whose component parts form neither definite chemical compounds nor isomorphous mixtures; those whose metals form definite chemical compounds; and those which do form isomorphous mixtures.

THE water flowing from the Sutro tunnel furnishes power for an 18-foot undershot wheel. It is 11,600 west of the mouth of tunnel. The wheel runs an air compressor which supplies drills in the Zadig drift in the Brunswick lode on the Sutro tunnel level.

THE black oxide of manganese (pyrolusite or psilomelane), when sufficiently pure, is ground to a fine powder and is used in chlorination works in the generation of chlorine gas by the action of sulphuric acid upon sodium chloride in the presence of the manganese oxide.

THE most important constituents of phonolite are silica about 60%, aluminum oxide 20%, iron oxide 2.5%, potassium oxide 5% and sodium oxide 9%. These proportions vary somewhat in different specimens. There are also numerous other constituents in small amount.

ZINC ore shipments from Colorado to Europe can not be deemed profitable at present prices. While spelter held up to $5.25 per 100 lbs. there was a slight margin, but at prevailing figures no freight rate from Leadville could make the shipments pay.

FAULTS and veins each are often found marking the course of a gulch or canyon, due to the fact that the rock on either side of the fissure, being softer and more shattered, was more easily eroded than the normal country rock, and a depression was the result.

THE recent shipment of the $5,000,000 in coined silver dollars from the Carson, Nev., mint to San Francisco was supplementary to a clearing out earlier in the year of about $2,000,000 gold and silver bullion, etc. The Carson establishment is now a bullion assay office.

GEORGIA furnishes considerable bauxite, or "aluminum ore." Such ore imported from France to Philadelphia and New York sells for $6.50 per ton. The easier solubility of the Georgia bauxite has obtained as high as $9 per ton for it at Syracuse, N. Y., and Pittsburg, Pa.

IN the early days of California quartz mining a great many overshot water wheels were built to furnish power to hoists and mills. Many of these were skillfully constructed under difficulties. One near Jamestown, in Tuolumne county, Cal., is said to have been nearly 60 feet in diameter.

RESPONSIBLE miners can usually be found who are willing to undertake shaft or other mine work at a fair price under contract, but the giving of bonds to insure the completion of such contract is unusual, though there may be those who would be willing to undertake the contract if price was satisfactory.

THE calorific value of gasoline is about 21,000 B. T. U. per lb; the usual guarantee of the manufacturer for engine use is about one pint per B. H. P. an hour. Under no circumstances should any considerable amount of gasoline be kept in the immediate vicinity of a mine, and wherever it is stored should be well ventilated.

THE Ontario mine, at Park City, Utah, which recently resumed operations after a long idleness, has produced $34,000,000 and paid $13,000,000 in dividends. Forty-five hundred gallons of water per minute flow through the lower drain tunnel, driven at a cost of $700,000. The pump in No. 3 shaft, costing $100,000, has been idle since the tunnel was driven.

WHEN in sinking a shaft it becomes necessary to change its angle from vertical to an incline, or, if an incline, from a stated angle to another, the change should be made on a curve of sufficient radius to permit the running of skips on this curve without slacking speed. A sudden change in direction when running rapidly may result disastrously and is always dangerous.

OUR Chihuahua, Mexico, correspondent, who has an important document so faded as to be illegible, can probably restore the color to the ink by bathing the paper in a solution of ammonium-sulphide. If this fails, gallic or tannic acid will probably bring out the words. After applying either solution, the document should be carefully rinsed and dried.

WHERE extremely volatile ores, like tellurium, are to be roasted in a reverberatory furnace, the fumes and dust containing high values may be thrown down and kept within the furnace by introducing a number of fine jets of water into the smokestack just above the furnace arch. This scheme has been successfully applied, in the roasting of telluride ores rich in gold preparatory to chloridizing.

THE descriptive term "Portland," as applied to cement, is only an arbitrary name for an artificial mixture. The name was first so used by a brick mason of Leeds, in England, who had made a cementing substance. On account of its close resemblance in color to a popular building stone taken from the Portland sandstone quarries of the English channel he called his invention "Portland cement."

THE Seven Stars mine, in western Arizona, crops for nearly 3000 feet, but in the entire distance casts no float. The vein quartz is crystallized, heavily mineralized and often presents a "comb structure." Where oxidation has taken place, the quartz disintegrates into sand and no pieces of float have ever been found. The croppings are very obscure on this account and are much mixed with the talus on the slope of the mountain side.

CHROMITE occurs massive and granular to compact. Its color is iron black to brownish black, translucent to opaque, sometimes feebly magnetic. It usually occurs in serpentine and varies greatly in value and size of deposit. Often the ore is largely composed of serpentine, seeming to indicate that for some reason the process of deposition had been arrested before it was complete. Ores of this kind can be readily concentrated.

THE corrugations on the rim of a silver piece of United States money are not the "milling." The "milling" is the little raised rim around and above the level of the sides to protect the surface from wear. The parallel notches or corrugations around the rim are called the "reeding." The latter term is adapted from its architectural use to express a small convex molding, especially when such moldings are multiplied, parallel to each other.

INVESTIGATION of the subject by the American Institute of Electrical Engineers regarding the relative economy of horse and electric delivery wagons goes to show that the average delivery wagon covers a distance of about 11,268 miles per year, at a cost of 13,86 cents per mile for a two-horse vehicle. An automobile would cover the same distance for 2,65 cents per mile less, equivalent to $298.60 per year. A further economy is the higher speed of the electric vehicles.

WHERE a mining claim is located over which a ditch has been previously constructed, the claim is taken subject to any easement existing at the time the location was made. The miner who locates a piece of ground must take it as he finds it, subject to prior rights, which have an equal equity, on account of an equal recognition from the Government. After such location has been completed the estate of the owner cannot be subjected to any additional burdens excepting for public use. The owner of the pre-existing ditch may go upon the later mining location for the purpose of repairing his ditch, but he cannot enlarge it without the consent of the mine owner.

THERE are two types of feed-water heaters, the open and the closed: in the open the exhaust steam comes directly in contact with the feed water; in the closed it does not. The object of the feed-water heater is to save fuel by making use of the exhaust steam from the engine to heat the feed water. A good heater of ample proportion should raise the temperature of the feed water to 200° F. Besides so heating the feed water, a good heater also purifies the water by extracting the scale-producing matter and mud.

WHERE the locator of a claim has failed to do the assessment work within the time specified by law, and goes onto the claim and resumes work before another sets up an adverse claim, the first locator can hold his claim as against another—provided he show his honest intention by completing the assessment work. It would be difficult to persuade the Government or any individual that the intention was to do the assessment unless the work were done. One's intentions are usually interpreted according to his acts.

A COLORADO reader writes that in his little town four copies of this paper are weekly received, in single wrappers, directed to residents, evidently sent by subscribers elsewhere, who, after reading the paper, send it to friends and acquaintances there, who, probably, after reading, pass the copies on to others elsewhere. It has been asserted, with some show of truth, that each issue of such a paper as the MINING AND SCIENTIFIC PRESS is read by three or four men in addition to the original purchaser or subscriber.

A CIRCULAR SAW, with diamond-pointed teeth, is used for sawing stone for buildings for the Paris Exposition. The saw is a steel disk, 6 feet in diameter, in the edge of which cutting teeth, crystals worth about $1.25 a carat, are fixed. For sawing hard stone the cutting edge has 200 diamonds; the speed is 300 turns a minute; it advances into the stone about a foot in that time. For soft stones the teeth are of steel, with diamonds at intervals of every five teeth. These saws cut and dress the stones on all sides at from one-eighth to one-tenth the cost of hand labor.

EXPERIMENTS are being made in several mills in Deadwood Gulch, at Lead City, Ragged Top, and on Squaw creek, South Dakota, with tailings by the cyanide process. For more than twenty years tailings have gone to waste down Gold Run, Bobtail, and Deadwood gulches, which contained 75c to $1.25 per ton. An effort is now being made to economically extract a portion of the values. The finer material is carried many miles from the mines, the discoloration showing plainly in the Belle Fourche river, thirty miles from the mines. The greater portion is deposited, however, within the first ten miles of the mills.

WHILE mining machinery has gone up in price, it is no higher, relatively, than any other class of machinery at present. Raw material used in its construction has advanced from 40% to 85%, and that necessarily occasions increase in cost to the manufacturer and to the purchaser. Every manufacturer of mining machinery is busy, and, hence, there would be a little delay in delivery of large orders. A man wanting a hoisting plant to sink 1,500 feet could not expect to have his order filled "right away," but could, probably, have what he wanted ready for delivery in sixty days. In mining machinery as in everything else, competition makes it impossible for any concern to make or maintain high prices, and if the present prices seem high to any intending purchaser, it is for the reason stated.

FOLLOWING is Dr. J. Loevy's advice in anticipation of a possible case of poisoning in cyanide works: "A quantity of pure peroxide of hydrogen, distilled water, and a Pravarz syringe should be kept in every cyanide plant, and all workmen on the plant should be made acquainted with the method of preparing a solution of the required strength and of injecting it subcutaneously—a practice which any sensible man can readily acquire. The peroxide of hydrogen should be kept in small bottles containing about one-half ounce, with tight-fitting glass stopper, and kept in the dark to prevent decomposition. Considering that provisions have been made in all large industrial establishments to render first surgical aid in the case of accident, I think that a provision as suggested above against cyanide poisoning is just as well called for in cyanide plants."

THE type of engine known as the automatic high-speed engine has a wide range of cut-off, from almost 0 to ¼-stroke; to avoid a long valve and a long travel, and thus secure a quick admission and cut-off of the steam, recourse is had to multiple admission valves. These valves are so constructed that when one of them is moved from midposition a distance equal to, say, one-sixteenth of an inch more than the steam lap, the width of the opening for the steam to pass through into the cylinder is one-sixteenth multiplied by the number of admisions of the valve. Thus, if the valve is a double-admission valve, and is moved one-sixteenth plus the steam lap from midposition, the port is opened a distance equal to $2 \times 1\text{-}16 = \frac{1}{8}$ of an inch. Double admission valves are common; there is also a quadruple admission valve used, made as flat valves and as piston valves, but all with a common object in view: to secure an early cut-off and quick opening and closing of the ports with a valve whose length and travel shall be short.

THERE being some doubt as to the effect of the Act of the last California Legislature in an attempt to repeal the mining law of 1897, our California inquirer is advised to also comply strictly with the law of 1897. A fissure vein is a vein occupying a crack or crevice in the earth's crust; all fissure veins are "true fissure" veins. A gash vein is one having limited vertical extent, and is characteristic of mica schist formations. Some so-called gash veins occurring in other rocks have been found to reopen into large veins in depth, the several ore bodies being connected by a mere seam. "Chute" is the name of a mechanical contrivance for the passage of ore, and "shoot" is considered a proper spelling of a word indicating an ore body. Where three locations are made in a common direction, joining, and all are on one vein, the apex of which passes through each of the three claims, each claim is entitled to all the ore lying within the end lines of the claim, and each may follow the vein downward on its dip within the planes drawn downward through the end lines even though extending outside of and beyond the side line of the claim.

Republic District, Washington.

Written for the MINING AND SCIENTIFIC PRESS.

Republic, Washington, is the seat of the newly created county of Ferry, segregated from Stevens, and is on the Colville Indian reservation, opened to mineral location several years ago, and which is to be thrown open to white settlers as soon as allotments to the Indians have been completed. The entire section encompassed by this reservation is well wooded with pine, fir, cedar and tamarack timber, is watered by the Columbia, Kettle and San Poil rivers and their tributaries, and, so far as prospecting discloses its mineral formations, it is shown to be a mining country of great possibilities.

That portion known as Republic district is thirty miles south of the international boundary line and about equi-distant from the Columbia river at Kettle Falls and the Okanogan river at Loomis—thirty-seven miles from each point. The district is reached by stage, wagon or horseback from several points on the Spokane Falls & Northern Railway. The generally traveled route is from Bossburg by stage via Grand Forks, B. C., making a trip of eighty miles. Another route is from Myers Falls, via Kettle Falls, across the mountains, by which the distance is about thirty-eight miles. A stage road is being established over the latter route. As the Crow's Nest branch of the Canadian Pacific Railroad is now completed to Grand Forks, it is probable that considerable of the travel to Republic will be by rail to the former place via Rossland and Robinson. From Grand Forks to Republic is about thirty-seven miles, over a fairly smooth road. The construction of a north and south railroad from a a point on the Great Northern main line, up the San Poil valley, through Republic, to the international boundary line, is deemed a probability, as the Great Northern Co. have a charter covering such route.

The Republic district is waiting for transportation facilities, whereby milling machinery may be more economically shipped in, and whereby her smelting ores may be shipped out. The proposed line—up the San Poil and down the Curlew—would put Republic ores within reach of smelters at Grand Forks, Trail, Northport and outside points. Republic ores, which are highly silicious, would smelt well with the characteristic copper and iron sulphide ores of the Boundary and Rossland districts. Were such transportation and smelting facilities accessible, it is conceded that a considerable tonnage of Republic ores would be smelted rather than milled. The great bodies of ore, however, range in value from $10 to $20 per ton, and the problem, which is still not solved to the satisfaction of all, is as to the method by which those ores of low and medium grades can be profitably treated. The one mill operating in the district belongs to the Republic Con. G. M. Co., and runs exclusively on ores from the Republic mine. This is the practical application of the Pelatan-Clerici process. The ores are crushed and ground, the pulp passing through an 80-mesh screen. There are eight cyanide tanks, in four of which there are anode plates, which turn on the center shaft. The bottom of each tank is covered with a copper plate, on which the mercury is deposited. By electric currents the gold in solution is precipitated on the mercury-covered surface. About thirty-five tons per day are thus treated, but the Republic mine is capable of producing from 200 to 600 tons per day, and experts for the company have been making determinations which are to decide as to the equipment of the contemplated new mill of large capacity. It is probable that they will adopt some modification of the cyanide process.

Cyanide operators from Colorado and Montana have been here to study the situation and test the ores, and it seems understood that as soon as a requisite tonnage of ore can be guaranteed from the mines cyanide reduction plants will be built for custom work. The Republic and Mountain Lion, the most thoroughly developed mines of the district, are providing their own milling facilities, and the other properties, while developed with an excellent showing of valuable ores, are apparently not in position as yet to guarantee a steady tonnage to a mill. The mill just contracted for by the Mountain Lion will consist of twenty stamps, with amalgamating plates and cyanidation facilities for the tailings. This recalls to mind the fact that from 40% to 50% of the ordinary run of Republic ore values can be saved by the amalgamating process. It is conceded by all that the gold is largely in the free state, but in exceedingly fine particles. The veins trend in a north and south direction, within the limits of a great mineral zone, opened from the Mountain Lion on the north to the Princess Maude on the south. The country rock is porphyry and granite and the vein matter consists of white quartz of fine texture, varying in width from a few inches to 30 feet.

In the district there are forty or more claims, besides the Republic and Mountain Lion, whose developments make an encouraging showing of ore. Among those having development which would enable them to become shippers, to a limited extent, were milling and smelting facilities within reach, I mention the following, though there may be others entitled to the same classification: Ben Hur, Lone Pine, Quilp, Surprise, Black Tail, San Poil, Princess Maude, Tom Thumb, Bodie, Morning Glory, Rebate.

The Mountain Lion is developed by an 800-foot crosscut tunnel, with 600 feet of drifting on the vein and an upraise of 350 feet from the tunnel level to the surface. Work has commenced on a shaft on the vein from the tunnel. The work in the mine aggregates 2000 feet. A compressor has been installed on the property and air drills are in use.

The Republic ledge, which outcrops along the crest of the mountain ridge, is opened by means of three crosscut tunnels, one from the west side of the ridge and the others from the east side, by all of which a vertical depth on the vein of 400 feet is attained. A tunnel—No. 4—is also being driven from the east side, which will cut the ledge at about 2300 feet from the tunnel entrance and 200 feet below the present lower tunnel workings. The three tunnels completed are connected by upraises and the ledge is extensively opened by drifts and stopes. Good progress is being made on the lower tunnel and the values and ledge conditions determined by it will be of importance to the entire district. The ores milled, it is claimed, have averaged from $60 to $65 per ton, but vast bodies of lower grade remain, blocked out, awaiting a cheaper method of treatment. In the earlier development of the Republic mine 1540 tons of ore were hauled eighty miles in wagons to the railroad station and shipped to smelters, from which a net average of $160 per ton was derived.

The Princess Maude, adjoining the Republic on the south, is developed by a 400-foot tunnel, 120 feet of drifting and a 40 foot winze on the vein. The pay ore is white quartz, with narrow bands of black sulphurets, the values being gold, with good values in silver. So far as the developments go the prospects are excellent.

The Ben Hur shaft, 160 feet in depth, is expected to strike the ore body at 250 feet, which has been opened at another point through a tunnel.

The Quilp tunnel is in 160 feet and there are 500 feet of drifting on the ledge, 200 feet of which is in pay ore running $10 to $20 per ton.

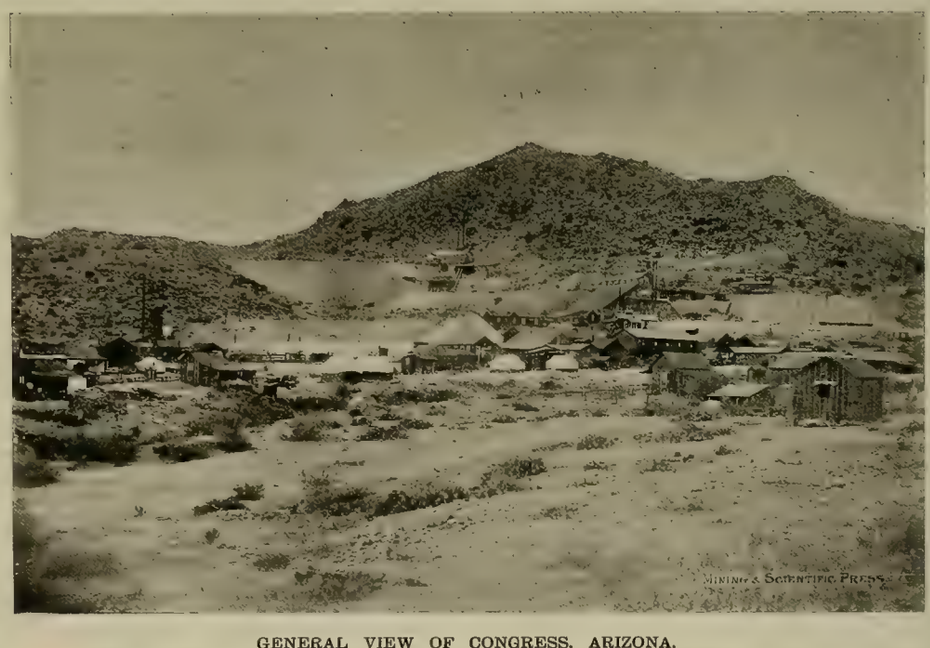
The North San Poil shaft, at 125 feet depth, is in an 8-foot ore shoot, carrying good values. It is on the same vein as the San Poil, the latter having a fair amount of development.

The Trade Dollar is in ore, having 400 tons of good grade on the dump.

The Bodie's incline shaft is 250 feet deep, from which drifting is being done on the vein. The values here average well.

Development on the Tom Thumb has reached a favorable stage, and that on the Rebate is being vigorously pushed. A shaft on the latter is 150 feet deep.

The Morning Glory tunnel has reached 250 feet from the entrance, from the level of which a winze sinks 85 feet on the vein. In the workings a ledge 6 to 8 feet wide has been uncovered, the paystreak being about 18 inches in width.



The town of Republic, though it has suffered from fires, continues to grow. It has picturesque surroundings and a population of about 3000. An electric power plant, driven by a 4-inch water wheel from a 1700-foot flume, a few miles from town, is to be put in operation for lighting purposes.

Republic, Wash., Aug. 21st, '99. WASCOTT.

The Congress Mine, Arizona.

Written for the MINING AND SCIENTIFIC PRESS.

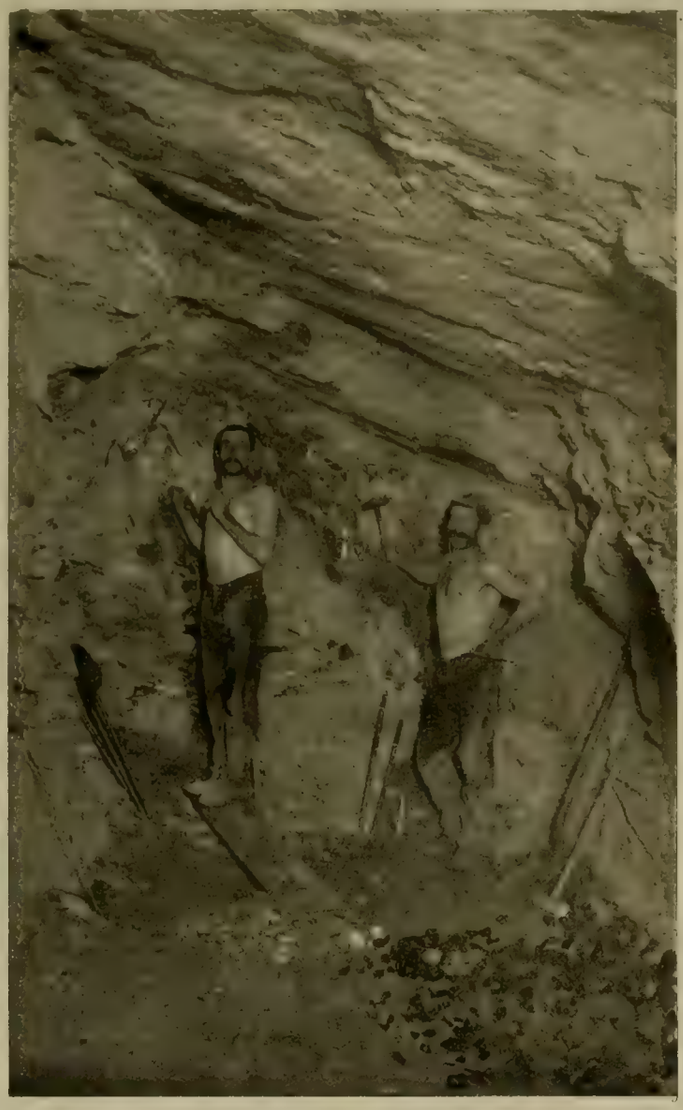
The Congress gold mine is in southern Yavapai county, Arizona, about midway between Prescott and Phœnix. The mine was discovered about twelve years ago and in its early history had several successive owners, eventually coming into the possession of "Diamond" Joe Reynolds, who equipped and developed the mine extensively before his death. It is now the property of the Congress Gold Co. and is one of the best appointed and most successfully operated mines in Arizona. In the early days of the mine's history some of the oxidized ore was noted for its light weight and high value in gold. Masses of spongy iron oxide with silica—the result of decomposition and leaching of the solid iron sulphide similar to that found at lower levels—were surprisingly light in weight, yet some of this material was worth over $600 per ton. The mine is equipped with a 40-stamp mill, has twenty concentrators and a complete cyanide plant. The concentrates are shipped to the smelters. The cyanide plant is provided with roasting furnace, and has a capacity of 100 tons daily. The surface of the tailings dumps is stirred by plowing to facilitate drying, which is quickly accomplished under the fervent sun of that clime. The dried lumps of tailings are carted by wheeled scrapers to a pulverizer, from which they are discharged by an elevator going to the furnace. The material is given a dead roast lasting four hours. Every care is taken to economize water. All the water used at Congress is pumped from Martinez creek, a mile distant, being elevated over a ridge 500 feet high. There is a large accumulation of tailings, the result of the operation of former years. The tailings as they come from the mill are a light gray in color. When they leave the cyanide plant they are red, the result of the oxidation of the iron sulphides in the roasting furnace.

GENERAL VIEW OF CONGRESS, ARIZONA.

The property consists of a group of twenty-three claims located along the strike of the croppings of the vein.

There are two veins—the Congress and the Niagara. Each is opened at a number of places. The main shaft is down almost half a mile, with no deterioration in either the size of the vein or its value. Two other shafts—the deeper 650 feet—are connected with the main shaft by levels. The mine is dry, and the item of expense so common in many mines—that of having to raise large volumes of water from great depths—is unknown here. The shaft follows the vein at an angle of about 30°. It is estimated that the total cuttings in the mine reach a distance of ten miles.

Two of the illustrations herewith give good underground views of the Congress vein. One at the 1850 level, the other at the bottom of the shaft when it was 1750 feet from the surface; each of which are characteristic scenes in a dry underground mine. The third illustration is that of the town which has grown up about the Congress mine.



The mines, mills and other company buildings are lighted by electricity, and there are many modern conveniences to be found scarcely to be anticipated in an isolated mining camp.

The mine and principal buildings are situated on a hillside, from which a magnificent view can be obtained of the far-reaching valley country beyond. Above the stretches of sand rise distant peaks and ranges, cut sharp and clean against a cloudless sky,

in an atmosphere so clear that hills 100 miles away seem near. Each of the distant hills and ranges is known to contain veins of gold, silver and copper. Indeed, there are few hills or mountains in Arizona where mines, or the promise of such, may not be found.

The Congress Co. has built at its own expense a railroad from the mine to the line running from Ash Fork to Phœnix by way of Prescott. This mine railroad has developed some startling feats in railroad engineering. It reaches the mine by a series of switchbacks, heavy gradients and abnormally sharp curves.

The town is characteristic of all mining camps in the great Southwest. It is divided into two sections—that at the mine and the lower town, in which the company has no interest. The contrast between them is marked. The buildings at the mine are neat and are arranged with symmetry and purpose. It comprises the company's offices, stores, bunk houses and homes of employes, etc. The lower town is built in a straggling line along the gulch, and contains buildings of stone and adobe and frame houses—adobes without roofs, tents, huts and lean-tos, a miscellaneous assortment of odds and ends. Still, Congress is prosperous. The lack of abundant water is a serious drawback to extensive building, as several serious fires have already visited the camp.

AT THE 1850 LEVEL, CONGRESS, ARIZONA, MINE.

Metamorphism of Rocks.

Written for the MINING AND SCIENTIFIC PRESS.

In their normal condition rocks are of two kinds, sedimentary and eruptive. These two great divisions cover practically all the rocks with which science is acquainted, but each of these groups is divided into several types of rocks, which have a somewhat different origin. For instance, sandstone and limestone are each sedimentary rocks but formed by different processes. Sandstone is the result of deposition of grains of sand derived from the degradation of older rocks. This material deposited on the floor of a lake, gulf or ocean, in time becomes indurated, and being uplifted by the movements of the earth's crust above the level of the waters, is called sandstone. The great limestone formations are mostly the result of the deposition on the floors of deep oceans of an infinite number of particles of carbonate of lime from minute organisms living in the waters. This deposit, in time being lifted above the sea, in consolidated form, is called limestone; beds of fine mud and clay are likewise uplifted and become shales.

BOTTOM OF SHAFT AT 1750 FEET, CONGRESS, ARIZONA, MINE.
From Land of Sunshine.

The eruptive rocks are of many kinds and occur in various forms. Those which are erupted and do not reach the surface are called intrusive or dyke rocks and are mostly of earlier geological age. Of this type are granite, diorite and some acid and porphyritic rocks such as quartz-porphyry, felsite, etc. Those rocks which have reached the surface and spread out over it in sheets are called effusive rocks. Most of the large granite exposures are undoubtedly due to uplift and erosion and in some instances to profound faulting and tilting of the rocks.

The metamorphism of rocks has always attracted the attention of geologists but it is only in more recent years that its importance has been realized. Large areas of rocks are now known to be altered from some previous condition, and the process is becoming better understood. This advance in knowledge has been made possible by the use of the microscope. Chemical analyses are important in determining the mineralogical character of rocks, but when employing this method the rock is reduced to powder and all opportunity to study its structure is lost.

The simple microscope will afford little insight into the true structure and composition of rocks, but the use of the polarization microscope opens a new field, and much that is otherwise obscure becomes at once plain and readily understood. Each mineral exhibits peculiar optical properties when viewed through the polarization microscope, which serve to distinguish it from other minerals in the same rock. For the purposes of microscopic study, slices of rock are prepared as thin as tissue paper. These are mounted between two sheets of glass, secured in position by Canada balsam.

Viewed without the aid of the polarization apparatus (which consists of two Nichol prisms made from the variety of carbonate of lime, known as Iceland spar, placed one above and one below the rock slide), many rocks present a most uninteresting appearance. There may be patches of dull green or brown and areas that are transparent, but that is about all.

Place the polarization apparatus in position and all is changed. The areas which were transparent, uninteresting objects before are now found to possess brilliant chromatic coloration, and in some of them a most beautiful symmetrical lineature is seen. These latter are the feldspars. Quartz polarizes in high colors, also mica, selenite and many other minerals. Rotate the stage of the microscope and a kaleidoscope of changing color is seen. Each mineral, as previously stated, is identified by its behavior under the microscope, and by this means the mineral constituents are recognized and the rock classified accordingly.

Not less important is the relation to each other of the crystals or fragments composing the rock. In such rocks as rhyolite, for example, the crystals of feldspar are seen to be surrounded by the curving wavy lines of the original molten ground mass. The magma flowing around the crystals, which appear as obstructions, turning the current aside. The hornblende of a diorite is found altering along the edges to chlorite, and around its border is a black fringe—an accumulation of grains of magnetite.

A slide of fresh, unaltered diabase is placed on the stage. Each individual mineral composing the rock stands out distinctly. The striated feldspars are easily identified and the crystals of augite present their characteristic cleavage, color and other features. Here and there is a grain of olivine, and throughout the mass is scattered many grains of black, opaque substance with sharp angular outline. The most of it is magnetite. Another slide of rock from the same vicinity is put on the stage. The same minerals are again observed, but some of them present a somewhat different appearance. The feldspars are observed to be cracked and dislocated. The augite crystals are distorted, drawn out and a green border surrounds each crystal. An investigation of a band specimen of the rock from which this slide was made shows it to be slightly schistose.

Another slide of this series is examined. The green color of the rock is present but the feldspars are still further fractured, drawn out and have assumed a greenish tinge. The augite has all turned to green hornblende, and is fibrous, the cleavage having disappeared. The edges are chlorite; small patches of calcite are observed; and so with each constituent, a change is noticeable. Again, an examination of a specimen of rock from which this slide was cut shows it to be a greenstone schist.

A specimen is chosen from the same vicinity which is a typical chlorite schist. The slide representing this rock on examination is found to consist almost wholly of fibrous hornblende mineral and scales of chlorite with a granular admixture of calcite, feldspathetic material and quartz, all having a green color. All of

these rocks were taken from a single area and within a few feet of each other. The transition from the normal granular diabase to chlorite schist has been noted and the microscope has shown the cause of this alteration. At first the rock was evidently subjected to a severe crushing force which fractured the crystals and grains composing the rock. The next specimen showed that owing to a movement of the rock mass these fragments were drawn apart with a slight alteration of the edges; the fourth specimen indicated that the force that had created these changes had progressed further and that the individual fragments were being drawn out and flattened still further and the rock was becoming a schist. The last specimens simply exhibited the complete alteration to chlorite schist.

Diabase has been selected for example because that rock is so frequently altered to greenstone schist. Diorite is altered in the same manner, but when completely altered and no rock of the original type can be found it is difficult to determine whether the rock was originally diorite or diabase. This alteration of massive rocks is called metamorphism, and the process by which it has been accomplished is known as shearing. Large areas are found consisting wholly of greenstone schist and slate, a microscopic study of which shows that the entire series of these schistose rocks owe their condition to compression and shearing in the manner described, with a consequent alteration of the individual minerals composing the original rock.

In the same manner granite is altered to gneiss and by further alteration passes over to mica schist; large masses of felsite become slaty with the development of secondary mica, and some sandstones and conglomerates also became schists. A bed of sand is found changed to hard, dense quartzite. An investigation of a thin slip of the rock shows each individual grain of quartz to be surrounded by some kind of cementing material. In some cases it is iron, in others, carbonate of lime and in still others each grain of sand is seen to be surrounded by an envelope of crystallized quartz due to the infiltration of silica. This is not at all uncommon but it was never suspected until revealed by the polarization microscope.

The changes produced in rocks by their metamorphism is much the same whether the alteration be limited to a relatively small area along a vein, fissure or contact, or whether it cover many square miles of territory. When the change is limited to a small area it is called local metamorphism, and is due to some dynamic force operating in the immediate vicinity. Examples of this type may frequently be observed where a fissure occurs in massive greenstones and the rocks on one side or both sides of the fissure are found altered from normal granular rocks to schistose or slaty condition. Where the alteration has taken place over a broad area it is called regional metamorphism and is due to some great force in nature which has subjected an immense volume of rocks to great pressure accompanied by movement, which at first fractures, then elongates the grains, and finally alters them to other minerals, the same process, in fact, as that already described, though more extensive. In metamorphism new rocks are not made but old ones changed.

Contact metamorphism is the result of the influence of the intrusion of an igneous rock upon a sedimentary or an older eruptive rock. The character of contact metamorphism varies with the character of the rock and to some extent with the kind of rock intruded. The intrusion of an igneous mass into limestone often results in its alternation to a crystalline condition forming marble. Slates often become semi-crystalline and develop foreign minerals in the form of distinct crystals, such as chiastolite and andalusite; shales are compressed and baked into dense, hard jaspers; quartzites are found to have developed a porphyritic structure; sandstones become vitrified into quartzites, etc. Contact metamorphism may be confined to a narrow strip along the intrusive rock or it may extend back from the intrusive rock for several hundred yards. Where granite has been intruded into contact with schistose rocks which lie parallel to the contact, the region of metamorphism is often broad, it being impossible to discover a line of demarkation, both the granite and the schist having been metamorphosed. When this occurs it may usually be found to be due to pressure and movement and a consequent shearing of both rocks. In some cases no alteration at all is found along portions of such a contact, without any apparent reason. When an eruptive rock cuts across the edges of an older formation the eruptive is often found to include many fragments of the older rocks, though the alteration of the older rocks is not so pronounced usually as when the contact lies parallel with the strike of the older rock. Metamorphism often wholly destroys the original sedimentary planes of rocks, the slaty cleavage and joints being entirely independent of sedimentation. The deposition of ores in sedimentary formations such as limestone and quartzite may be called a species of metamorphism but is usually the result of replacement—the substitution of an atom of ore for an atom of original rock, or it may be simply an infiltration of mineral into the interstitial spaces of the rock, as cinnabar in sandstone.

The metamorphism of rocks has a bearing upon ore deposits, for wide experience has shown that ore bodies seldom occur in rocks which have not been altered more or less. There are exceptions but these are comparatively rare.

Rand Deep Levels.

By JOHN YATES, Johannesburg, S. A. R.

The question of how best to work the great area of the deeper levels of the Witwatersrand is a matter in which the future of Johannesburg and the Transvaal is very intimately connected. So far our attention has been fully occupied in nibbling at the fringe of the reef—for in view of the operations of the future our present deepest mine does not carry us beyond this—but having now completed arrangements for working the outcropping edge, we are at liberty to devote attention to the exploitation of the body of the reef, a task which we have a strong inducement to undertake in the knowledge that satisfactory results are reasonably certain. But, as Mr. Miller indicates in his paper, the question is not how can the reef be worked, but, what is the best method of attacking it? To win a large area of the deeper reef presents few, if any, great difficulties, being well within our resources, but how to win it so as to secure a profit—the greatest possible profit—is a matter which, to a large extent, only time and experience of the new conditions will enable to be decided.

In taking up this problem it would appear that, as it is unlikely that there will be any necessity for material departure from the present methods of blocking out the reef for stoping, it resolves itself mainly into a matter of shafts, their position, number, and size, and the method of hoisting in them.

The features of the auriferous banket beds of the Rand are such that there is no reason to apprehend that their extent to the dip is very limited; on the contrary, the evidence available practically places beyond doubt that they will continue in depth far beyond a point where high temperature will render mining operations impossible. Where is this limit of work as fixed by temperature likely to be? Mr. Seymour has informed us that specially conducted experiments have discovered a rise for 1° F. for every 203 feet of vertical depth. If, therefore, we assume that the average temperature at a depth of 1000 feet is 72° F., that the maximum air temperature in which men and boys can do a shift's work is 100° F., and that this corresponds (say) to a rock temperature of 125° F., we find that the limit of work by temperature is 12,000 feet vertical, so that unless we are favored with a series of upthrow strike faults—a not unlikely contingency—the pegging of claims more than four miles from the outcrop will probably prove a waste of both time and money. In the headings and rises the difference between the temperature of the rock and that of the air is not likely to be so great, owing to the less perfect ventilation, and for these, at a depth of 12,000 feet, compressed air or other means of cooling the atmosphere would be needed to create a bearable temperature.

In shaft sinking the temperature would also be less than 12,000 feet vertical; the imperfect ventilation and the presence of a crowd of men and boys will probably make it 7000 feet—a limit, which, of course, could be extended by supplying the sinkers with cooled air, but it is open to question whether men and boys will be easily found who will sink vertical shafts to a depth of even 7000 feet.

In view of the fact that the practicability of working at a depth of 5000 feet is not infrequently questioned, the idea of working to a vertical depth of 12,000 feet will, I am afraid, be generally regarded as too visionary to call for serious discussion, but future operations will disillusion those who think that our limit is going to be anything like 5000 feet vertical.

The idea of seeing miners at a depth of 12,000 feet shivering in a cold draught is at present calculated to raise a smile, but things are moving so fast and so many impossibilities have become possibilities that it takes a venturesome man to predict what things we are not going to see in the future; but no matter how much the probability of reaching 12,000 feet vertical may be doubted, the possibility of the thing cannot safely be ignored in the laying out of our next deeps. It is not unlikely that our third row of deep level mines will have vertical shafts of about 5000 feet. Between these shafts and the 12,000 feet vertical limit there will be 14,000 feet of reef, as measured on the line of the dip, assuming the latter to be 30° and the formation undisturbed.

Owing to the enormous cost and the difficulties attending the sinking of very deep shafts, together with the possibilities of heat limiting the maximum depth of verticals to 7000 feet, I take it that it is improbable that more than one row of shafts will be put down south of the 5000 feet series. But the question arises: Cannot the whole of the reef down to the heat limit be best tested and worked through these 5000-foot shafts, and is stage winding in vertical shafts likely to assume the importance Mr. Miller appears to imagine? In order to discuss this, I will assume that it is practicable to put down a 9000 feet vertical shaft, that the third row of deeps with their 5000 feet shafts have 8000 feet of reef measured on the dip, the reef leaving the property at 9000 feet vertical, and that from this to the 12,000 feet vertical limit constitutes a fourth row of deeps, with 6000 feet of reef on the line of the dip.

Present operations having placed the prospects of 5000 feet deeps practically beyond doubt, these might be taken in hand without delay; but it is not likely that a 5000-foot shaft for the fourth row is going to be started without some positive evidence of the value of the ground at that depth. Such evidence could be obtained either by a borehole—though to put such a hole down would probably tax our resources to the utmost—or by the sinking of the inclines of the third row of deeps.

Testing by borehole, though very convenient, is unsatisfactory where such enormous interests are at stake. Their disclosures are too local and too limited. On the other hand, the incline shafts of the third row of deeps would not only indicate, with some approach to accuracy, the size and value of the reef at the lower depths, but also the temperature, the quantity of water, and the nature of the formation likely to be met with, whether disturbed or not; in fact, they would yield information which would enable prospects to be judged almost to a nicety. These considerations are strongly in favor of testing by the incline shafts. But it might be urged that to do this would inconveniently delay the opening up of the lowest deeps. This, however, is not the case, provided that the shafts of the third deeps are put down with a view to also serving the fourth deep, and thus doing away with the need for verticals on the latter. Calculating on the present rate of sinking in the stiffer ground of the Central Rand—rates which will undoubtedly be improved on in the future—the sinking of the verticals and inclines of the third row of deeps would take: 5000 feet vertical at 90 feet per month, 55.5 months; 8000 feet incline at 100 feet per month, 80 months; total, 135.5 months; while to put down a 9000-foot vertical shaft—assuming it possible—on the fourth deeps, to reach the same point, would, allowing 75 feet per month, take 120 months, or practically the same time; in other words, the reef of the fourth and final row of deeps can be reached and opened up as quickly by the verticals and inclines of 5000 feet deeps as by vertical shafts sunk within their own boundaries—presupposing that there is no material upthrowing of the reefs by reverse faults. This is favorable to working such fourth deeps through the shafts of the thirds, or, to go a step further, to having the third row of deeps work to the heat limit, opening them up in a manner comparable with the claim area, and thus having the full number of stamps allotted to this area dropping much sooner than would be the case if the claims were divided into independent third and fourth deeps.

The total length of incline working to the heat boundary through the 5000-foot shafts would be 14,000 feet, so that winding in four stages in this distance would probably suffice and constitute a satisfactory working arrangement. Doing all the hoisting through the 5000-foot shaft would be a little more costly for power than having the 9000 feet vertical for the lower section of the reef, inasmuch that the ore from this section would be pulled 8000 feet along the incline instead of 4000 feet vertical; but against this there would be the saving of wages and of maintenance due to there being one shaft instead of two.

It will be noticed that this idea of working out the reef to the heat limit through 5000 feet verticals would do away with the need for stage winding in verticals, for Mr. Seymour has steadily informed us that one stage winding from this depth not only can be done, but is an accomplished fact. It is not that there are any engineering difficulties connected with stage winding in verticals, but I think that although stage winding on inclines would give every satisfaction, it should not be introduced into verticals except where absolutely necessary—the simpler we can have vertical hoisting the better. There would appear to be nothing simpler than one stage rope hoisting, and about 5000 feet is apparently the present limit for this, so that by having shafts of this depth, with one stage hoisting, we apply the maximum of power direct, thus avoiding some of the loss connected with the transmission of power to motors underground.

(To be Continued.)

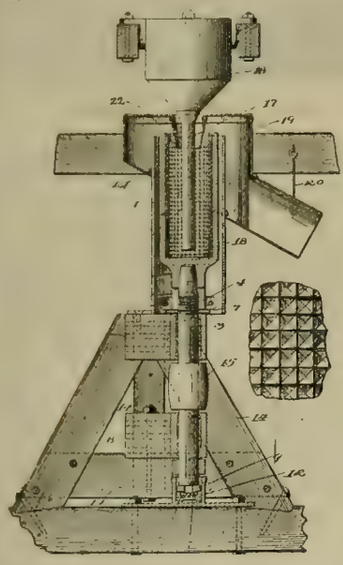
Volume and Head of Water.

The following table will give information of value to miners and others who may want to know how many miners' inches of water they will require to have a certain head of water for a certain-size nozzle:

Head, feet.	*Miners' Inches*				
	2-in nozzle.	*2½ in.*	*3-in.*	*4-in.*	*5-in.*
100	80	125	185	322	500
150	100	155	225	400	625
200	115	180	260	460	715
250	130	200	290	515	800
300	140	220	320	565	880
350	150	240	345	610	950
400	160	255	365	650	1000

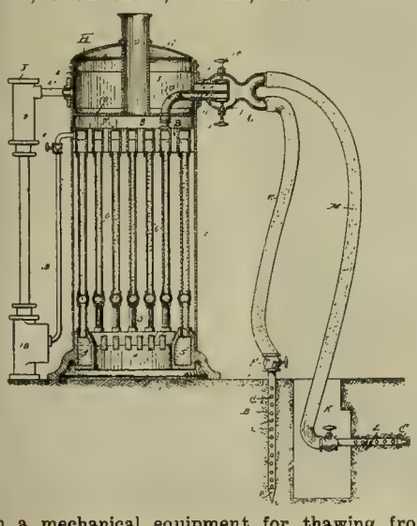
Latest Mining and Metallurgical Patents.

Patents Issued Sept. 5, 1899.



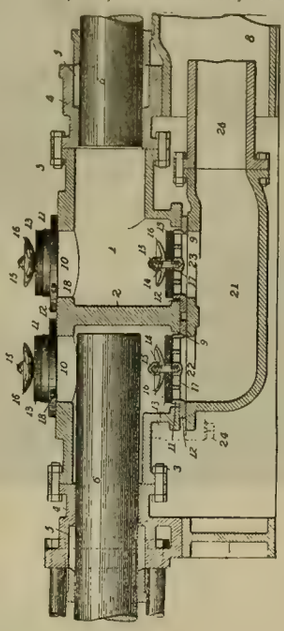
Specially Reported for the MINING AND SCIENTIFIC PRESS.

PUMPING APPARATUS FOR OIL WELLS.—No. 631,776; J. H. Cook, Pittsburg, Pa.



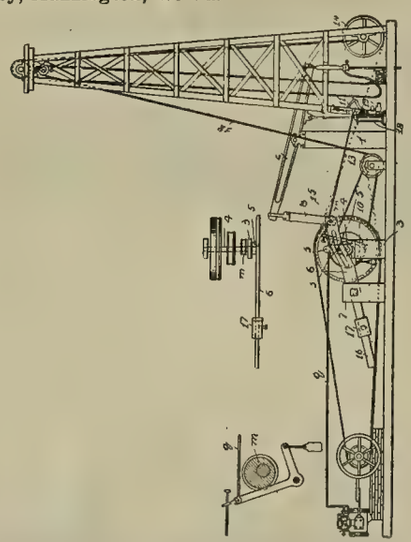
A working valve for an oil well pump consisting of the tube 21, the cups 10 arranged thereon, the glands 17, the divided packing rings 14, the springs 16, the upper cage 23 and valve 22, the divided frame 8, and pin 5 attached therero.

ORE CONCENTRATOR.—No. 632,338; E. Clark, Denver, Colo.



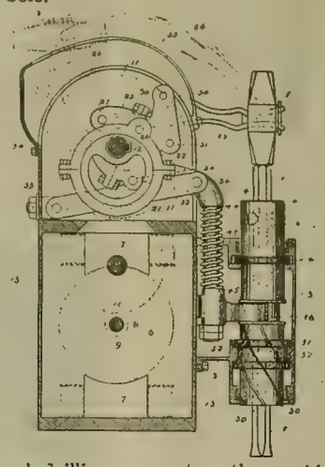
A lining for the walls of an ore-concentrating chamber, having series of pyramidal pockets extending into the lining at right angles to the axis. The combination of a vertical centrifugal ore concentrating chamber and a vertical removable lining having pyramidal pockets extending from the face of the lining to the wall of the chamber.

APPARATUS FOR THAWING FROZEN GROUND.—No. 632,388; J. Whitehead, Urbana, Ohio.



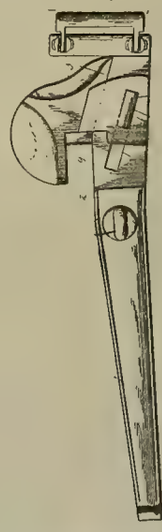
In a mechanical equipment for thawing frozen earth the following apparatus: A steam generator and an air heater consisting of a shell with a fire box near one end, and a water and steam head, an air chamber above head, a steam and air cock connected with head and air chamber, a steam pump with its operating cylinder connected with head and its pumping cylinder connected with air chamber, a flexible pipe connected with cock adapted to receive steam or air according to the adjustment of the cock, a heating pipe connected at one end with flexible pipe and pointed at the other and having perforations through a portion of its length and insertible in the earth throughout the perforated portion and a part of the imperforated portion, whereby a special apparatus is formed for alternately applying steam and air, and an effective distribution of such medium against the frozen earth is effected without leakage of the medium between the earth and heating pipe.

PUMP.—No. 632,428; J. B. Poore, Scranton, Pa.



In a pump, the combination with the water barrel having an inlet opening in its lower side and a suction chamber beneath barrel and removably secured thereto, of a valve within the opening and having a seat adapted to be clamped between barrel and chamber, and supports for holding valve in place when the chamber is removed. A horizontally arranged water barrel having two chambers, and pistons adapted to operate through the opposite ends of barrel, of an inlet opening in the lower side of each chamber, a suction chamber beneath opening and removably secured to barrel, a valve in each opening having a flanged seat adapted to be clamped between the suction chamber and the barrel, and supports for holding the valves within the openings when the chamber is removed. The combination of two stuffing boxes, a support for each, a water barrel arranged between and supported by the stuffing boxes, and two pistons, one arranged in each of the stuffing boxes and adapted to operate in the water barrel between boxes.

WELL-DRILLING MACHINERY.—No. 632,537; C. F. Rigby, Mannington, W. Va.



In well-drilling machinery, the combination of a crankshaft carrying a crankpin, a cable-actuating lever fulcrumed to reciprocate vertically, the lever having an elongated slot in which the crankpin operates, the outer portion of the slot being disposed transverse the path of the pin's travel when depressing the lever, whereby the latter is given gradual downward movement, and the slot portion 9′ or that part nearest the lever-fulcrum, disposed at an angle to slot portion 9 so as to more nearly coincide with the path traveled by the crank in its ascent, thereby causing the lever to rise at accelerated speed, the parts being so constructed and arranged that the point of divergence of the slot portions is reached by the crankpin after the lever finishes its downward reciprocation and before it begins to ascend, whereby the lever and cable have a perceptible rest, and torsional strain of the latter incident to sudden reversal of movement is avoided.

ELECTRIC ROCK DRILL.—No. 632,658; G. W. Pickett, Denver, Colo.

In a rock-drilling apparatus, the combination of drilling mechanism having a reciprocating movement of its rock-cutting parts, an electric motor having a rotary movement of its armature in one direction, and gearing connecting the armature-shaft of the motor with the drilling mechanism and provided with a friction clutch adjusted so as to transmit the power of the motor to the drilling mechanism but to slip or yield at or about the times when the movement of the reciprocating parts is reversed. A drill supported in a holder and having longitudinal movement therein, a reciprocating hammer arranged to strike the head of the drill, mechanism for reciprocating the hammer, an electric motor, and connecting gearing between the motor and the hammer-operating mechanism.

WRENCH FOR WELL-DRILLING TOOLS.—No. 632,555; C. L. Dunham, Center View, Ohio.

A wrench involving the combination of a lever having a straight portion to form one jaw of a wrench, a face inclined with relation to straight portion, an elongated shot in a plane parallel with the inclined face, a flanged jaw adapted to slide backward and forward over the inclined face, and a key for coupling the lever and the movable jaw.

THE operation of gravity tramways is dependent upon a natural and accelcrating force—the loaded car descending the inclined plane draws the empty one upward, but there is a loss of force. Cut the car loose at the top of the incline and it starts toward the base, slowly at first but with accelerating speed until it dashes to destruction at the bottom. If it were possible a falling body would in time assume a velocity equalling that of the planets in their orbits but the limitations of distance do not permit it.

Folsom-Sacramento, Cal., Transmission Plant.

At a special meeting June 10th, '99, of the Franklin Institute, B. C. Washington read a paper on "Water Power Electrical Plants in the United States," in which prominent place was given to the Folsom-Sacramento, Cal., transmission plant which has now been operating successfully since June, '95. It is of interest to note that the first sawmill in the world operated wholly by transmitted electrical power is run by current furnished by the plant in question. Engravings of the sawmill appear on this page. Reference is made to this mill as it particularly illustrates the difference between theory and practice, and the fact that commercial success is the test in this as in everything else. The mill herewith illustrated was the first in the world to be run wholly by electricity. It has been idle for a long time and when it does start again steam power will be used, at least as an auxiliary. So far as the electrical equipment is concerned it worked perfectly and is a complete success in normal seasons when sufficient water is obtainable. But the ordinary refuse and offal of a sawmill that is usually burned became in this instance a problem. Instead of being utilized as fuel to make steam, the slabs, sawdust, etc., became a source of expense, for, as the pile accumulated, the State Fish Commissioner compelled its being kept out of the river. Prohibitive freight rates precluded the sale of the sawmill's refuse in Sacramento or elsewhere. So that when this sawmill is again in operation the electrical equipment will probably be supplemented by steam generation of electrical power.

THE FOLSOM, CAL., SAWMILL — FIRST ONE IN THE WORLD RUN WHOLLY BY ELECTRICITY.

The mill is part of the general equipment of the American River Lumber Co., which, by its foothill and mountain connections, will be ultimately able to put logs into the Folsom dam for $4 per M. Mr. Washington, in his article, gives some technical data of interest in connection therewith: The water power of the American river is utilized for driving the generators. The water supply of that river presents some peculiar features, as the flow of water is derived from new sources at all seasons of the year. In the late spring and summer months the melting snows in the mountains bridge over the dry season, and later, as this source of supply is on the wane, the rainy season sets in. The foundation of the dam was begun thirteen years ago by the Natoma Water & Mining Co., and on this foundation, in 1888, the transmission company began the work of completing the dam. The river is confined for several miles by high granite hills, which, where the dam is erected, form a natural point for the building of such a structure. The dam contains 30,000 cubic yards of masonry; the headworks about 15,000 cubic yards. The storage capacity of the dam is about 13,000,000 cubic yards of water. The shutter is a trussed timber platform, which rests in a masonry recess running longitudinally along the top of the center of the dam. When lowered, it is secure from damage by floating debris. The shutter is operated by five hydraulic rams. The sand gates each cover an opening 5x6 feet through the wing dam, and are at the end of the dam to prevent sand or gravel from passing into the canal and causing injury to the water wheels. The bottom of each gate is 8 feet below the bottom of the canal; a short distance farther down the stream a wall 8 feet high is built directly across the canal. The inlets to three of the gates are tunnel-like openings covering the width of the canal. The openings are 8 feet below the bottom level of the canal. The headgates are operated by hydraulic rams. Both the primary and secondary coils of all the step-up transformers are worked in parallel, taking current at 800 volts from the generators and delivering it to the lines at a potential of 11,000 volts. Each generator is provided with a separate and distinct circuit from the power house to Sacramento, and can be worked singly or in parallel. A double-pole line, 22.75 miles long, follows the road. The poles are of cedar, 12 inches at the top, 16 at the butt, and are set 6 feet in the ground, fifty-two to the mile. The cross-arms are braced with angle irons, and are 4x4 inches in cross-section and 7 feet long. The

ANOTHER VIEW OF THE SAWMILL AT FOLSOM, CAL., RUN WHOLLY BY ELECTRICITY SUPPLIED BY THE FOLSOM-SACRAMENTO ELECTRIC TRANSMISSION PLANT.

transmission circuits are supported on double-petticoat porcelain insulators tested to withstand a potential of 25,000 volts. The pole lines each support six No. 1 B. & S. bare copper wires, which effect the transmission at an estimated loss of 10% at full load. A telephone line is carried on one set of poles. The line is transposed every five poles. At the distributing station the transmission circuits are led direct from the pole lines to the step-down transformer chamber, in which are located the various transformer equipments. Three large 250-kilowatt synchronous motors are supplied with energy from 125-kilowatt transformers, which deliver current at 500 volts. The other transformers step-down to 125 volts, the current being distributed over the city on a four-wire system, consisting of three wires for the 3-phase current and a fourth or neutral wire. The incandescent lighting service is rendered by extensions made between either of the three wires and the neutral, proper care being taken to keep the circuits balanced within reasonable limits. The power service is rendered directly from the 3-phase wiring. Large motors are operated from 500-volt, 3-phase wiring; the 125 and 250-volt, four-wire system is used for small motor work and incandescent lighting.

Telegraphing Without Wires.

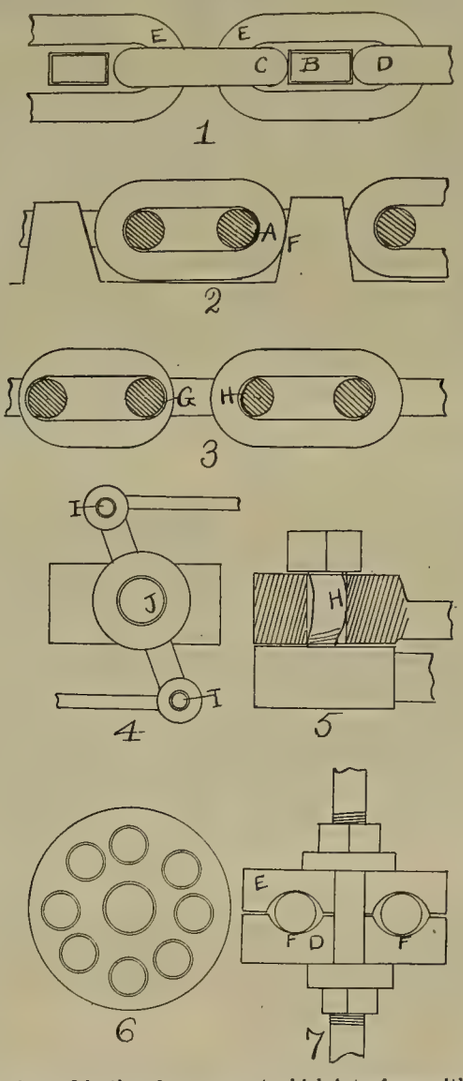
During the Columbian Exposition at Chicago in 1893, an invention for wireless telegraphy by induction was brought before the International Congress of Electricians by W. H. Preece, electrician to the British Postoffice; Nicola Tesla is understood to be engaged in an invention on a new system; and other inventions and experiments are noted; but the lead in practical success so far seems to have been taken by G. Marconi, a young Italian, who in 1896 made some remarkable experiments at Spezia, Italy, and later came to London, where his invention was examined and approved by Mr. Preece. During 1897 and 1898 Marconi succeeded in telegraphing from the shore of the British Channel to a vessel at different points, at a distance of several miles, and even despite the intervention of high headwinds; and in April, 1899, messages were successfully transmitted across the British Channel from a point near the South Foreland lighthouse to a French station near Boulonge.

Marconi is said to use static or Faradic electricity of very rapid vibration, (the line of frequency of oscillation being probably about 250,000,000 per second) rather than the ordinary electric current of commerce; and he is thus able to produce vibrations in the ether of space. These etheric vibrations would be in every direction but for a contrivance of "reflectors," which send them in the direction desired.

The receiver, to which they are transmitted through the ether, consists essentially of two silver poles set in the ends of a glass tube about two inches in length, within which is a vacuum as nearly perfect as can be made, while the metallic ends extend within the tube toward each other, and are separated only by an almost infinitesimal distance, within which are fine filings of nickel and silver with a trace of mercury. The current of etheric vibration being received at one pole of this apparatus is strong enough to throw the fine filings in this vacuum into polarized arrangement, when they at once form an electric conductor for a current of galvanic electricity connected with the receiver's poles by a local circuit, and this local current instantly sets in motion a small hammer, which taps upon the tube and by jarring breaks up the polarized arrangement of the filings as soon as the polarizing influence of the etheric wave ceases, so destroying their power of conduction. Thus by an alternating conductivity and non-conductivity of the filings of the local circuit is made and broken, and signals are conveyed, the resumption of the current being audible in the tapping of the local sounder for sound reading, while the same current can also record Morse signals on paper by ink.

To the objection that the message thus transmitted could be read off by any receiver, and so all privacy destroyed, it is answered that the transmitter and receiver are "tuned" to a key of corresponding vibrations, a phenomenon of electric vibration which may be compared to the tuning of musical strings or tuning forks to the corresponding pitch, so that the sounding of one will excite to sound the other also.

A conspicuous part of both the transmitter and receiver is a perpendicular wire, the height of which to get the best results should vary with the square of the distance. The electric current being broken by an ordinary Morse key, sparks pass between two brass balls which cause a succession of electric waves in the ether. These would naturally spread, like the waves of light, in every direction; but they are directed by a copper reflector, as light by a mirror, towards the receiver, and there received by the sensitive apparatus described.



Other electricians besides Marconi are connected with the development of wireless telegraphy. All make use of theories of electric currents published by Henri Hertz 1887. In Paris, M. Ducretet has established posts at different points within the city; in Berlin, Prof. Slaby has connected the top of his house with the laboratory of the Technical School, and with Potsdam, over twenty miles of distance; and the Russian electrician, M. Popoff, has communicated between a shore station and vessels at sea.

General Greely, of the U. S. Signal Service, says that many experiments and tests show that great delicacy and constant adjustment are required in the receiver, so that the transmission of signals and messages is as yet uncertain and unreliable; though the value of the system between ships at sea, instead of the ordinary flag signals, is sure to be manifested.

Topics for Coal Miners.

Written for the MINING AND SCIENTIFIC PRESS by GEO. S. RICE.

Chain drives on hauling systems and power transmission in coal mines require special care if good work is to be expected. Figs. 1 and 2 are sketched to illustrate some usual faults in chains, with which the mining engineer has to contend. The tendency is to use a too heavy lubricant and apply it to such an extent that caking results; hard, crusty fills of hardened mixture of grease and foreign matter collect at *E*, Fig. 1, and likewise on the other links of the

chain, and in time form a crust which interferes with the free working of the chain. The writer has found chains in such condition from this crusting of grit and oil that the corresponding links are forced against the teeth *B* in the sprockets, producing binding at *C* and *D*. This is shown in Fig. 2, in which *A* marks a collection of the foreign matter and *F* the place where the link binds on the tooth in consequence. This trouble is frequent in chains which are exposed to the elements. The best kinds of oils or greases produce a good surface for dust, dirt and pieces of vegetable matter to cling to, and unless there are regular inspections and cleaning trouble is likely to occur. Even in boxed chains this difficulty happens. Some engineers partly overcome the clogging trouble by using very thin oils and applying them in such a manner as to clean out and wash off any dirt which may have gathered. I often find that the ill-working of a chain is due to the links being worn as at *G*, Fig. 3, or at *H*. In either case the remedy consists in the substitution of new links.

Shifters.—One of the shifters used in shifting from switch towers in coal mines is shown in Fig. 4. When this pattern binds it is usually due to the springing or bending of the central stud *J*. When the rod studs *I I* become bent, twisted, sprung, badly worn, clogged with old oil, or in any way out of form, binding will result and no more oil should be applied, but the worn parts should be substituted with new, and the parts which may have slipped or loosened should be readjusted. In the eccentric pattern of shifter, the failure of operation is ordinarily due to the uneven wearing down of the cam or the bending and consequent binding of the set screw *H*, Fig. 5.

Faulty Bearing.—Fig. 6 is a design of ball thrust bearing of recent construction, and presented here to illustrate how unreasonable some inventors of new forms of bearings are. Fig. 6 is a top view of the bearing, which consists of a plate or disk provided with openings for the steel balls. This bearing was completely covered with oils, time and time again, and yet proved non-effective in an elevator shaft in a coal mine. The reason is apparent. The balls are supposed to roll or turn on their axes on the step plates, and are retained in place by the retaining plate or disk. But certain laws of mechanics were overlooked in the planning of this pattern of bearing, for instead of a smooth, sliding or turning motion of the balls, the latter scrape on the sides of the openings in the retainer to such an extent as to produce undue friction. This results in a sort of a sliding frictional contact, and is not the neat rolling contact which would work well in harmony with a good lubricant, as is the case in a thrust bearing remodeled to the plan in Fig. 7. Here we have the balls *F*, *F* in grooves formed in the disks *E* and *D*, rolling under such conditions that each ball may revolve on its own axis, producing rolling contact without the necessity of being bound up in the retainer as in the first case.

Winding Cylinder Working Irregularly.—The following are some of the important reasons for a winding cylinder of a hauling system running unevenly: (1) Lack of perfectly free movement in the winding friction, either in the worm which is turned by the governing motion, or in the worm placed within the arm of the quadrant. This latter may become bent near the top and give trouble; or the upward play of the worm may become arrested occasionally, and so shorten the length of chain; or there may be too much upward play of worm, allowing it to rise when the quadrant arm gets to a forward position of about 55 degrees, thus suddenly lessening the strain and as quickly catching it again. (2) The set screw on the winding drum gear getting loose, preventing it turning readily. The stud, holding spur gear to the winding drum, may also become loose. (3) Winding drum gear may not be set true. It should be set parallel with the axis of the cylinder. (4) Carriages striking out or in too hard, or striking in too easy. (5) Squaring bands too slack. (6) In backing off, the faller should gently follow the unwinding of the chain.

Observations on Rock Drilling.

TO THE EDITOR:—The Miners' Union gave a picnic at Stent, Tuolumne Co., Cal., on Labor Day. One of the main attractions was the drilling contest, the first prize of $100 being won by Page & Wainright of Sonora, who drilled 37 15/16 inches double-handed in fifteen minutes, stone used being Rocklin granite. This remarkable record was made with first-class American drill steel. The second best drilling was done with imported high-grade steel, while the poorest of all was done with drills made from the highest priced tool steel in the market, which goes to show that hammered steel is the best for percussive rock-drilling tools, and a steel which may be superior to any other for making chisels and lathe tools for cutting iron may be unfit for rock drills.

Extra care is taken with the tempering of drills to be used in drilling contests, as a broken drill or a battered one may lose the driller his match. None but the most experienced past masters in the art of tool dressing are considered fit to temper the "chisel-pointed" thin-as-a-knife-blade bits used in exhibition drilling. The maker of the drill bit, although usually overlooked, is entitled to as much admiration for his skill as is the miner whose true, rapid and sturdy blows, shedding a shower of sparks at each impact of the hammer, drives the drill through the solid granite. C. L. LANG.

"DID you ever see a double-barreled tunnel?" inquired a well-known resident of the news-gatherer. The latter had not, and wanted to know what a double-barreled tunnel was. The gentleman addressed said: "Well, when I was over near Salton, California, in July, I went to the mines, and in one place I noticed that the party developing the property had opened two tunnels and that there was not 6 feet space between the face of the openings. Why the owners did not crosscut I cannot say, but it struck me that whoever run those tunnels had "wheels," and had 'em bad. There are mining men whose proper place is behind a ribbon counter." With the last remark the speaker gave expression to his feelings by uttering a pronounced grunt, added to which was a liberal supply of swear words.

A NEW steel shaft just finished for the Boston Elevated Railway Co. is said to be the largest ever cast. It is to be used in the company's central power station. The engine will be of 4000 H. P. at ordinary speed. The shaft is 28 feet in length and 38 inches in diameter in the center, and weighs about 75,000 pounds.

Prominent Achievements in Metallurgy.

Of the achievements in metallurgy which have either been actually effected or are in immediate prospect Professor Sir W. Roberts-Austen recently gave the following collective statement in his presidential address to the Iron and Steel Institute of Great Britain. There are, he said, blast furnaces which will produce 690 tons of pig iron in twenty-four hours, with a consumption of little over 15 4 cwt. of coke per ton of iron, and the gases of blast furnaces are used not only as sources of heat, but directly in gas engines. There are Bessemer converters which can hold 50 tons of metal, and open-hearth furnaces which will also take 50 tons, while 100-ton furnaces are projected. The open-hearth furnaces are fed with one ton of material in a minute, by the aid of a large spoon worked by an electro-motor. There are gigantic "mixers," capable of holding 200 tons of pig iron, in which, moreover, a certain amount of preliminary purification is effected. Steel plates are rolled of over 300 feet in area and 2 inches thick, and there are girders which justify the belief of Sir Benjamin Baker, that a bridge connecting England and France could be built over the Channel in half-mile spans. There are ship-plates which buckle up during a collision, but remain water-tight. There are steel armor-piercing shot which will penetrate a thickness of steel equivalent to over 37 inches of wrought iron. The points of the shot remain intact, although the striking velocities are nearly 2800 feet a second. There are wires which sustain a load of 170 tons per square inch without fracture. Hadfield, whose labors he hoped to see continued far into the twentieth century, has given us manganese-steel that will not soften by annealing; while Guillaume has studied the properties of certain nickel-steels that will not expand by heat, and others that contract when heated and expand when cooled. Nickel, chromium, titanium and tungsten are freely used alloyed with iron, and the use of vanadium, uranium, molybdenum, and even glucinium, is suggested. Huge ingots are placed in soaking pits and forged direct by 120-ton hammers, or pressed into shape by 14,000-ton presses, and there are steel castings for parts of ships that weigh over thirty-five tons. —Cassier's Magazine for September.

Electrolytic Separation of Cadmium From Iron.

A method for separating these two metals in slightly acid solutions is described in the *Zeitscrift fur Elektrochemie*. As a cyanide solution gives the best deposits of cadmium, certain experiments have been made with the idea of finding out whether such a solution could not be used for the electrolytic separation of iron from cadmium. When an excess of cyanide of potassium is added to a solution of a ferrous salt, a soluble ferrocyanide of potassium is formed. With solutions of ferric salts, hydrated peroxide of iron is produced, and only a very small proportion of iron passes into the cyanide solution. The method proposed is based on the non-electrolytic decomposition of the soluble ferrocyanide of potassium. The mixed salts of iron and cadmium are dissolved in 100 c. c. of water very slightly acidulated with a few drops of dilute sulphuric acid; to this is added two or three grammes of pure cyanide of potassium, and the whole heated until the solution becomes perfectly clear. If this clarification requires too long a time, a few drops of caustic potash may be added. The solution is then diluted to 200–250 c. c., and, after cooling, electrolyzed with a current of 0.05 to 0.010 ampere per square decimeter. The deposit of cadmium is perfectly coherent. If the solution contains but a very small quantity of iron, the floating hydrated peroxide may be neglected; but if, on the contrary, the iron is present in any considerable proportion, it becomes necessary to reduce this ferric salt to the ferrous state by means of a sulphurous acid; to effect this it suffices to add to the acid solution a small quantity of sulphite of soda, and heat for a short time.

Output of Iron Mines.

A prominent iron ore miner says the Lake Superior region will ship 16,000,000 tons of iron ore this season. His estimate for the mines tributary to Duluth–Superior is 7,500,000 tons. The local furnaces, such as those at New Duluth, Ashland and Escanaba, will probably receive some ore during winter, but Pittsburg and Chicago will be supplied during the season of navigation.

The ore shipments from the Lake Superior region will be divided as follows:

Vermilion and Mesaba, 7,500,000 tons; Gogebic range, 2,500,000; Marquette range, 3,000,000; Memoninee range, 2,500,000.

Shipments from the Lake Superior region last season were about 13,600,000 tons. The Minnesota ranges and the Gogebic range are the ones that will provide the increased ore tonnage this year. Practically all of it will be from the Minnesota ranges. There will be an increase of from 1,900,000 to 2,000,000 tons from the entire Lake Superior district, and the Minnesota ranges will furnish about 1,400,000 tons of the increased shipment. The Marquette and Menominee ranges will just about hold their own this year as to output and shipment. The Gogebic will show a fair increase, but Minnesota is the bulwark of the iron ore consumers this year with their great demands.

The Vermilion range, which last year shipped 1,200,000 tons, will this year ship 1,800,000 tons. The Iron Range road will handle 4 000,000 tons this year; the Mesabe road 2,500,000 to 3,000,000 tons, and the Eastern about 1,000,000 tons. Shipping over the Eastern will become heavier after the Sauntry mine begins operating and the road is extended to it.

Next year there will be the same demand as this year for ore, and will probably be greater. But the mines will be in better shape to produce the ore, and the transportation facilities will also be increased. There will be more boats and more ore cars to meet the emergencies of heavy shipping, and the whole scheme of production and transportation of, say, 16,000,000 tons of ore, will be more easily accomplished than this year. Prices for ore will certainly be better than those at which the bulk of ore was sold this season. The big sales were made before the boom in iron and steel commenced.

Ishpeming *Iron Ore* quotes Joseph Sellwood as predicting that the State of Minnesota would send out 8,000,000 tons of ore this season, and thought the entire region would furnish about 16,000,000. The big mines are not always going to hold out. The constant drain at the present big volume makes serious inroads. There are many worked-out properties on the older ranges, and some of the new fields are already feeling the effects of big shipments.

A DELICATE instrument, designed by Horace Darwin, will indicate slow tilts and pulsations of the earth's crust of less than one three-hundredths of a second, or an angle less than 1 inch in 1000 miles. It consists of a circular mirror suspended from brackets by two wires of very unequal length. Slight tilting of the upright causes exaggerated motion of the mirror. The spot of reflected light will vary ½-inch when a finger is laid on the support of the apparatus.

THE wavelike appearance seen on the faces of some sandstones and shaley rocks when broken from their beds is due to either the rippling of water or the action of the wind. The marks thus made have been preserved in the rocks by subsidence of the formation beneath the waters and subsequent deposition of other material upon the bottom of the lake or lagoon. The process may be seen in operation on the shores of a low, marshy shore or on the heaps of drifting sand along the shores of some lakes and the sea.

The Assay of Foreign Lead Ore.

An important decision regulating the sale of foreign lead ores was handed down recently by Judge Hanford of the Federal Court of the State of Washington, in the case of the Puget Sound Reduction Works, operating the Everett Smelter, on appeal from a decision of the United States Board of Customs Appraisers in New York City.

Judge Hanford holds that, under the United States laws, what is known as the "fire" assay shall be used to determine the amount of dutiable lead in imported ores, and gives the smelter company judgment against the United States for the amount of excess duties paid on ores shipped to it under the ruling of the Washington officials that the "wet" method should be used in assaying such ores.

Under the new ruling, the Government will be compelled to change its system of assaying imported ores for the purpose of obtaining values on which to figure duties. In the past the official system has been the "wet" or chemical process. It is contended and generally acknowledged that this process yields about 2% more lead than the fire system. The smelter people fought the case and won on the theory that the commercial method is the fire assay. The decision settles the question as to whether the wet or the fire assay is the commercial method by declaring that the evidence is satisfactory and convincing in favor of the latter.

Judge Hanford had the case under advisement and handed down a written opinion. Reviewing the evidence, he says, in part:

"It would require a very strained construction of the law to find that Congress, after having in 1894, and again in 1895, enacted statutes requiring the sampling and assaying of ores, for the purpose of collecting duties thereon, to be according to commercial methods, and without having expressly repealed the law of 1896, could have intended in the law of 1897 to continue the same policy as regards the methods of sampling and yet departed from that method for the purpose of assaying.

"It is my opinion that the Secretary of the Treasury is required, by the positive provision of the Acts of Congress above referred to, to prescribe regulations for the assaying of lead ores by the commercial method, is a question of fact, for the decision of which resort must be had to evidence.

"In this case the evidence is all one way and it is in all respects satisfactory and convincing. From it I find that the commercial method of ascertaining the quantity of lead contained in imported ores is the fire process, and any other method of assaying does not meet the requirements of the law."

AN old wagon bridge which has spanned the Wabash river, near Clinton, Ind., for half a century has been removed by aid of the electric current. The county bought the piers, the principal owner agreeing to remove the superstructure to make way for a new bridge. Efforts were made to burn the bridge, but it was found that this would injure the piers, so the sills were wired and electricity applied. In nine hours the pile toppled into the river, leaving the foundations unhurt. The current had the effect of cutting all the sills simultaneously as with so many saws.—Electricity.

The oldest iron steamship in the world is the United States steamer Michigan. The vessel was constructed at Pittsburg, Pa., in 1841–43; the parts were transferred to Erie, put together, and launched on December 5, 1843. The original machinery, with the exception of the boilers, is still in her and in good condition. The vessel is an iron paddle-wheel steamer of 635 tons displacement; length of keel, 156 feet 4 inches; length between perpendiculars, 162 feet 6 inches; breadth of beam, 27 feet; depth of hold, 12 feet 5½ inches.

Rare Brazilian Sand Used for Incandescent Mantels.

The monazite or Prado sand, which is used in the manufacture of the Auer incandescent mantels, says the London *Electrical Review*, is found at Bahia, Porto Seguro, and in small quantities in Matto Grosso, Brazil. In the first two places the sand is found close to the shore and is derived from the decomposition of the neighboring gneiss. It is of a dark yellow color, like gold, and very heavy. The following is an average analysis:

	Per Cent.
Aluminum	3
Cerium	62 to 70
Iron	2½
Lanthanum	2½
Thorium	1½ to 8½
Yttrium	1 to 2

Cerium is an extremely rare metal, hitherto found only in Sweden. Its color is a whitish-green, and it has considerable metallic luster. Its specific gravity is almost equal to platinum. Mixed with copper and zinc, an artificial gold is produced, having the same luster and weight as real gold.

Thorium is of a gray color, and when burned in air or oxygen is converted into an oxide. The metal combines energetically with chlorine, sulphur and phosphorus and dissolves in hydrochloric acid, liberating hydrogen in the process. As may be supposed, there has been a considerable run on these valuable sands since they were discovered, and it is expected that the value of this current year's exports will be more than double what it was last year.

Thirty-three Miles of Aluminum Cable.

The Hartford Electric Light Co. of Hartford, Conn., has ordered thirty-three miles of aluminum cable. The company is building a concrete dam in the Farmington river, at Tariffville, Conn., eleven miles from Hartford. From this waterfall it will realize 2300 H. P., which will operate two 1000 H. P. generators, giving 10,000 volts. This current is to be transmitted over aluminum cables to the company's power station in the city of Hartford. There will be three cables for transmitting the current, strung in the form of a triangle on double crossarms and double insulators. The wires will be left bare and will run to within a mile of the city limits, when the current will be reduced to 2400 volts, at which voltage it will run to the company's city generating station, where the current will be transformed to a lower voltage for power and lighting purposes.

Each cable has seven strands, and each strand is made up of seven wires of No. 11 Brown & Sharpe gauge. The complete cable is about 1 inch in diameter, and has a conductivity equal to No. 0000 copper wire. Aluminum is to be used in the high-pressure transmission line only, and by utilizing the light metal instead of copper the company estimates that, with present prices for copper, it will save $3500. —Electricity.

THERE is no data available which would furnish anything like a reliable estimate of the extent of the underground workings of the Leadville, Colo., mines, but the sum total must be enormous. For twenty years the hills have been honeycombed with underground drifts, and the work is still progressing. For the past two or three years from five to six miles of new work have been done in the Ibex mine, and there are now upwards of forty miles of workings in that property alone. There are about twelve miles of workings in the Chrysolite, and at least as much in the R. E. Lee. The Carbonate hill mines have honeycombed that hill very thoroughly, while Iron hill has been burrowed through to an enormous extent. It is safe to say that if all the drifts, levels, winzes, upraises and shafts in Lake county were represented by a continuous tunnel, it would represent an underground passageway of over 1500 miles. There are some calculators who can figure out that there are at least 2000 miles of workings.

Mining Summary.

ALASKA.

The last monthly reports of the Alaska-Mexican and Alaska United mines show results as follows. The former crushed 14,936 tons ore, valued at $19,679, and turned out 200 tons sulphurets, valued at $10,201. The ore averaged $2 20 per ton. The gross earnings were $32,178 and the working expenses $19,-. The latter mine crushed 24,144 tons, valued at $45,725, and yielded 645 tons sulphurets, valued at $20,165. The ore averaged $2.52 per ton. The gross earnings were $65,8-6. One of the mills, dependent [illegible],765 and the working expenses were upon water power, had to hang up some of its stamps five days during the month because of the short supply.

Juneau *Miner*: The following are the values of Alaskan and British Yukon gold:

	Per oz.
Little Manook, American	$19 50
Small, Cape Nome	18 50
Ophir, Golovin Bay	18 50
Bunker, Klondike	17 00
Pine, Atlin	16 75
Wright, Atlin	16 75
Dominion, Klondike	16 75
American, Eagle City	16 75
Porcupine, American	16 75
Bonanza, American Yukon	16 75
Bonanza, Klondike	16 30
El Dorado, Klondike	15 50

El Dorado carries the poorest quality of Yukon gold, and Little Manook the richest. The highest assay returns from Yukon gold were from gold taken from No. 8, Little Manook, owned by former Governor J. H. McGraw and Gen. E. M. Carr. It ran $19.63 per ounce. The American Cape Nome is high grade. El Dorado gold has run as low as $15 per ounce, as high as $17.09 per ounce has been obtained from discovery claim on the American Porcupine Creek.

ARIZONA.

MOJAVE COUNTY.

The 20 stamp mill at the Sheep Trail mines, near the Colorado river, is running.

The C. O. D. mine on Stockton hill is again working. The old dumps are to be milled and concentrated.

W. J. Shick of New York has commenced work on a large hydraulic plant in the Ehrenberg district for the purpose of working the Chrego placers. Water will be pumped from the Colorado river, five miles, and the plant will handle 2000 yards of gravel per day.

YAVAPAI COUNTY.

(Special Correspondence).—R. A. Thomas, of the Black Hills Copper Co., has arrived at Jerome from Los Angeles, for the purpose of initiating the work of the newest Jerome company. All matters pertaining to the organization are reported satisfactorily consummated.

Several boarding houses and bunk houses have been put up at the Iron King and Copper Chief properties, which are as yet in the hands of the Chinese. At the Copper Chief nothing new is reported. The Iron King is working in the lower tunnel. The surveyors have completed the new pipe line from Allen's diggings and within thirty days will begin laying pipe.

Jerome, Sept. 9th, '99.

CALIFORNIA.

Amador.

The Oneida mine, between Jackson and Sutter Creek, makes 400,000 gallons of water daily.

R. Porter is making good headway in the shaft of the Mutual mine, south of Amador City. The shaft is in a slate formation full of quartz and sulphurets. This is the newest large enterprise in Amador.

E. Purington, formerly superintendent of the Gover mine, near Amador City, has bought the Loyal Lead, near Drytown.

Amador *Ledger*: Bryson & Worthing, of the Abe M. & M. Co., have a bond on the C. Kretcher property, south of the Bay State mine. It was opened many years ago and a drift test returned $4.65 per ton in free gold. A tunnel cut the Bay State ledge and all the Kretcher ledge, though the latter was not noticed. A drift south shows that the come together 25 feet from the original tunnel where the ledge is 12 feet thick of good value in free gold with 4% sulphurets. They will sink a vertical shaft.—At 300 feet in the old shaft, a crosscut was driven to the Kretcher vein, from which valuable ore was milled. At the 750-foot level crosscutting to the Kretcher ledge is in progress, now in 340 feet.

Butte.

J. S. Trowbridge, at the Robinson mines, is putting up a new hoist building. A boiler and a double-cylinder hoist for sinking 1000 feet have been added, and power drills will be used. The shaft is down 100 feet below the creek level. There are 1400 feet of tunnel on the ledge above the collar of the shaft. The 20-stamp mill has been rebuilt and ten stamps will run.

Calaveras.

It is reported that the Lucas mine, on the Mokelumne river near Big Bar bridge, has been sold to the owners of the Tomboy mine in Colorado, Posey & Co., for $20,000. The purchase price was paid down. The new owners express a purpose to expend large sums of money on the property.

F. F. Thomas, president and manager of the Gwin mine, accompanied by J. McSorley, visited North Branch recently and examined the Hudson, Mester and Jackson mines, near Central Hill.

The Hudson vein lies at a low angle and a vertical shaft was sunk through it by early operators. Development work has been done on the mines lately.

Jackson *Dispatch*: High grade ore in the Derrest mine, near Fourth Crossing, is coming from the 400-foot level.—At the Barstow mine, near Glencoe, a new hoist and mill are being erected. The mine was recently sold in England.

San Andreas *Prospect*: At the Lightner mine in Angels, Supt. H. G. Murray will sink the main shaft now down 450 feet to 650 feet. The 40 stamp mill is crushing 208 tons of ore in twenty-four hours.

Angels *Echo*: The new hoisting machinery is in position at the Harris mine, a mile south of Angels, and the gallows frame is completed.

Inyo.

It is reported that a Vermont marble company is negotiating for the Lindsey marble quarries east of Antelope.

The Anthony group of mines in the Panamint range is reported sold for $45,000.

Kern.

Three shifts are rushing development work at the Butte mine at Randsburg.

Bullion returns on 1800 tons of ore crushed at the Red Dog mill near Randsburg amounted to $41,267.

Randsburg *Miner*: From a run of thirty-seven tons of ore the Kinyon mine owners received $11,000, and from twenty tons of second class ore milled they received $1000. One hundred and forty tons of ore taken from the dump averaged $8 a ton.—The Yellow Aster Co. has eleven men working at the wells drifting. They have encountered another good flow of water. At the mine 152 men are employed - 137 in the mine and twenty at the mill. The payroll runs over $13,000 per month.

Marin.

Near Bolinas, oil deposits are reported on the outskirts of the town. J. D. Bradbury of San Jose has bonded several ranches and has ordered a plant and will commence sinking wells. Oil was first discovered near Bolinas several years ago by R. Coltingham. On the beach, among the rocks, natural gas is found. When the tide is out, on Duxbury Reef, the gas rushes out of the rocks, when lighted it will burn until extinguished by the tide. Ledges of asphaltum have been discovered on the beach.

Nevada.

The shaft of the Bismarck & Gladstone mine, near Selby Flat, is to be sunk an additional 100 feet.

Grass Valley *Union*: Steam was started on the old Union Hill mine on the 8th inst. for the first time in many years. The pumps are in operation. Sinking will be begun and old drifts cleaned out.

Grass Valley *Union*: Supt. Brockington reports work progressing favorably at the Omaha, Homeward Bound and Lone Jack mines under his direction. Sinking was commenced at the Omaha and drifts are being run in both directions at the bottom.

Placer.

The Jupiter mine, near Iowa Hill, cleaned up $2200 for August, the result from drifting.

At the Sailor mine, in Sailor canyon, where a large amount of money has been expended in search of a gravel channel, a new tunnel has been started, on the advice of N. A. Harris, 400 feet higher than the old workings. It is thought the channel will be found in 350 feet.

Nevada City *Herald*: A carload of rich copper ore was shipped from Sheridan to the smelter last week.——Prospectors on Bear river are finding rich ground at 30 to 50 feet depth with augers.

Plumas.

Oroville *Register*: Steam-power drills are to be used in the Robinson mine in Granite basin, and a new hoist is being put up. A new water wheel has been put in, which will give more power than the one formerly in use. R. C. Robinson has two shifts working and expects to strike ore this week. Men are building 2300 feet of flume to carry 250 inches of water, which will be used to run an 8-inch hydraulic elevator.—San Jose capitalists are to open what is known as the Elizabethtown channel mine.

San Diego.

Miners are investigating the gold-bearing veins near Campo, in Laguna mountains.

Ex Receiver C. W. Pauly of San Diego has petitioned the court for privilege to work the tailings of the Golden Cross mill at Hedges. There is a large amount of this material accumulated and it all contains value in gold.

San Joaquin.

The Golden Gate Oil Producing Co. has been incorporated at Stockton. W. R. Thomas, D. O. Castle, S. E. Lotta, W. J. Rhodes and S. M. Spurrier. Capital stock, $100,000.

Santa Barbara.

The St. Valentine M. Co. has been incorporated at Santa Barbara. W. Ealand, G. F. Treuwith, J. H. Burson, A. C. Grant and C. A. Stork. Capital stock, $100,000.

Santa Clara.

The Gay Quarry Co. has been incorporated at San Jose. W. A. Porter, C. Wehner, G. Lion, J. W. Rea, A. C. Darby, A. Greeninger and T. W. Hobson, San Jose. Capital stock, $50,000.

Shasta.

(Special Correspondence).—The Coronado Copper M. Co. of San Francisco is developing a large area of territory twenty-six miles southwest of Redding, in the neighborhood of the Bully Choop mine. The company owns 400 acres. J. Blumenthal is president and R. Mohr secretary. A contract was recently let to run 400 feet of tunnel, which is calculated to cut the ore body at a depth of 280 feet. A 60-foot shaft opened a vein which was crosscut 18 feet without finding the walls. The contract price is $5 per foot.

Basset & Welch are running a new tunnel in the Eureka mine near Shasta. They found a third ore body on this property, which assays $22 a ton.

Behrns & Lievasay are working seven men on the Oro Fino mine near Shasta. This mine has had many operators in the past few years. The present company has found the ore body so long sought. The values are from fair to high grade.

The recent transfer of copper properties at Furnaceville and Copper City has stimulated prospecting in those sections and almost every available claim has been located.

In the neighborhood of Kennet about sixty claims have been relocated (jumped) since the announcement of the news that the last Legislature did not repeal the Act of '97.

Redding, Sept. 13th, '99.

Experiments are to be made with the ore of the Yellow Rose of Texas. The gold bearing material is talc and clay and does not crush readily under stamps.

That there has been unusual interest in mining in this county the past year is shown by the number of locations filed for record during the past twelve months as compared with the number during the twelve months preceding. From Sept. 7, 1897, to Sept. 7, 1898, 1134 locations were filed with the County Recorder. From Sept. 7, 1898, to Sept. 7, 1899, the number was 1735 an increase of 551.

Shasta *Courier*: A number of men employed at the Mount Shasta mine have been laid off and sinking on the ledges is in progress to open ore deposits on lower levels. At the Old Bunker Hill mine development is in progress. Rich rock, carrying tellurium and free gold, has recently been discovered in a defined ledge. The mine is two miles south of Shasta and is owned by Mrs. J. Loag of New York, J. V. Scott and others.

Sierra.

Downieville *Messenger*: Articles of incorporation of the Twin Eagle M. Co. have been filed with the County Clerk. The capital stock is $50,000. The directors are J. C. Hastings, J. S. Wilbur, F. S. Gould, E. McGary, Jr., and J. McGary. The company is preparing to operate the Gray Eagle mines on Kanaka ravine. A mill recently purchased in Nevada county is on the ground, and construction work commenced. J. S. Wilber, Supt. Gray Eagle mine, near Gold Point, is at the mine and has commenced grading for the mill.

Siskiyou.

The Greenhorn Blue Gravel mine has been purchased by A. & L. J. Wetzel, J. E. Harmon and W. R. Ridenour, who intend sinking a new shaft and adding apparatus for working on a more extensive scale. John Garvey will continue as foreman.

The group of quartz mines on Squaw creek, a tributary of Willow creek, in the Gazelle district, promises to turn out well. The mines show a ledge 98 feet wide, and have been bonded to Dr. G. W. Dwinnell, of Montague, for $45,000, the agreement being that quartz yielding $30 a ton or more be shipped to Keswick and lower grade ore stacked until a mill is put up.

A four-mile ditch is to be dug from Buckhorn creek, a tributary of Horse creek, on Klamath river, to the Poverty Point and Yankee placer mines opposite Oak Bar.

W. A. Bantz started up the mill on the Little Tiger mine at Greenhorn last week, but has shut down to make alterations in machinery.

Mr. Rader, who bought out the Hunter-Johnson quartz mine at Horse creek, on Klamath river, has been finding rich prospects. The sulphurets contain gold, but have to be sent to the Selby works.

Yreka *Journal*: The company working the mine at Greenhorn on the Nehrbass place, adjoining the Blue Gravel mine, are down 130 feet, which indicates that it is in a deep ancient channel.—Work is to be started again on the cinnabar mine at the head of west fork of Beaver creek, by the Siskiyou Con. Q. M. Co. Mr. Newcomb has been at the mine lately, making arrangements for starting with fifteen men.—The ledge at the Golden Star or Spencer mine, on Humbug creek, is rich but small.——G. W. Foote, working the Merrimac mine on Humbug, has a rich ledge.

Tuolumne.

Sonora *Independent*: J. Meighan has men grading for the 20-stamp mill on the Mt. Jefferson mine, at Groveland.—A new station in the Accident mine of Big Oak Flat has been cut and drifts driven. The ledge is 21 feet wide. The property is managed by J. Meighan.—Rich ore is being taken from the Republican mine at Jacksonville. Byrne & Herndon have bought the Ophir mine, near Big Oak Flat, from Mr. King, and will erect a mill.——C. Hall has returned from Placer county and has resumed work on the Golden Eagle pocket mine in Big Oak Flat. At the Pauper's Dream, formerly the Accident, in Big Oak Flat, they are down 260 feet in good ore and are drifting on the 100-foot level in $20-rock.——The Mississippi mine, at the lower end of Big Oak Flat, has started up again.—At the Nonpareil shaft, near Deer Flat, ore bins are being built. The shaft is down 80 feet and sinking in good ore.

Sonora *Union-Democrat*: Forty five men are constructing a dam on the Stanislaus river, four miles below Robinson's Ferry. When completed an electric plant is to be put in and power sold. The enterprise is owned by C. D. Lane & Co.——At the Bown, near Robinson's Ferry, ten men are drifting on the cross-vein at the 300 and 400 levels. The quartz at these points has a width of 3 feet of ore.——Work on the Alameda, near Rawhide, which was to have been resumed, has been indefinitely postponed. The entire force was laid off Saturday.—Three shifts are making 15 feet a week in the Arbona shaft at Tuttletown, in hard rock. No crosscutting or drifting will be done until 600 feet is reached.—The Norwegian, near Tuttletown, has closed down on account of lack of water, and will not resume until the first of the year.

COLORADO.

BOULDER COUNTY.

Staples & Eddy have attached the Ward pyritic smelter, claiming $580 for work, driving the tunnel on the St. Louis mine, which is under bond and lease to the smelter company.——The upraise in the San Blas, connecting the lower workings with the surface, will be completed next week. A body of ore has been opened in the upraise and shipments will be made.

The B & M. is driving the 150 450 and 600 foot levels west, and is shipping three carloads of smelting ore per week. The leasers on the Ni Wot have two carloads of concentrates ready for shipment. The Ward Rose will soon be in operation on development work. J. Machlebrenner of Pittsburg, one of the stockholders, will superintend the work.

CHAFFEE COUNTY.

(Special Correspondence).—The D. & R. G. R. R. main line runs within four miles of Turret and a branch runs to the Calumet iron mine through the camp, giving good railroad facilities. Buena Vista has a smelter eighteen miles distant and Salida is to have a 200-ton smelter fourteen miles from Turret. Assays of the camp range from a trace to $2500 in gold per ton, and it is nothing unusual to get assays of from 10 to 30 ounces in gold per ton. The formation is graphic granite, the veins are hematite and copper, copper, pyrites in most cases running with them, the dykes being 3 to 50 feet in width. In depth copper appears in nearly all the veins and occurs in a variety of forms. The veins are of good width. It is two years since the first location was made here.

The Gold Bug has the deepest shaft in the district down 200 feet and is sinking to 300 feet. Shipments from this property range in value from $20 to $24 per ton in gold. It also carries copper and silver. The vein at the 100 foot level is 31 feet wide. A crosscut at the 200 foot station is being run to determine the width at that depth.

At the Holdridge, which is 75 feet deep, the smelter returns show the ore to run $92 per ton. Work is being pushed throughout the camp. The altitude is 9000 to 10,500 feet.

Turrett, Sept. 9th, '99.

The plans have been completed for a 60-ton smelter to be erected by the Salida Mining & Smelting Co.

Cree camp, near Monarch, is about to commence steady shipments. The Clinton mine has ore that runs $2 in gold, 64 ounces silver, and 20% lead. More than 750 feet of development has been done.

A new camp called Dawson has been formed near Cree camp, and ore taken from the surface assays from $180 to $200 to the ton in gold. A large number of claims have been located, and work is in progress.

CLEAR CREEK COUNTY.

The Newhouse tunnel is to resume work.

The Stevens mine recently made a shipment of ore that carried 60% lead, 30 ounces in silver, and $2 in gold to the ton.

The Johnson mine, in Argentine, recently had a mill run of ore that ran 387 ounces silver and 19% lead, worth $220 per ton.

Ore has been found in the Independence that runs 2370 ounces in silver.

F. W. Isham of Denver has a lease upon half of the dump of the Meadota mine at Silver Plume, upon royalties aggregating 20%. He operated in the interests of Denver mining men. This dump is one of the characteristic sights of Silver Plume, containing 80,000 tons of rock, carrying fair values in zinc, lead, gold and silver. The work of reducing the dump has been begun in the Dives-Pelican mill.

GUNNISON COUNTY.

The Hercules and Ajax properties are being worked above the tunnel. A mill run of concentrating ore was made last week. T. Nichols, of Denver, is opening the Denver City, on Sheep mountain, Crystal district. Copper ore is being taken out and shipment will be made. R. J. Walter and F. Kratzer are owners with Mr. Nichols.

O. Allen has made a proposition to the mine owners at Snow Mass, Crystal district, to put in a concentrating plant for the treatment of the mill dirt of the copper prospects in the vicinity.—A strike of rich copper ore has been made in the lower tunnel of the Burt mine. Native copper is found in the gangue.—The Scofield mill is now operating on ore from the Whopper.

LAKE COUNTY.

At the annual meeting of the Fanny Rawlings M. Co., owners of the Fanny Rawlings claim, on Breece hill, in the gold belt, held at Colorado Springs, it was determined to purchase a $10,000 plant of machinery and to deepen the shaft 200 feet. The mine commenced shipping in November, 1898, and $200,000 was the gross receipts up to April 1, 1899. Two dividends from royalties amounting to $20,000 have been paid this year. The lease is held by Taylor & Copeland of Aspen. The mine is shipping twenty five tons daily of gold copper ore to the Bi Metallic. This property had remained undeveloped since its location, twenty years ago. Manager J. F. Walsh has made a study of the occurrence of the Breece hill ore channels and developed the Fanny Rawlings.

Colorado zinc ores are of good value, but not as easy to reduce as the Missouri ore on account of the iron it contains. One large smelter works has a contract for several thousand tons of 50% zinc at $30 per ton. The Vieille Montagne Co. of Antwerp, Belgium, has made a flat contract for 5,000 tons of Colorado zinc at $5 per ton. F. O. B. Jacobsen & Co. of New York City, zinc brokers, are making purchases in this market and have wired to increase shipments. The Louisville will increase its zinc output as the stopes are opened.

The Greenback is drifting on the 1100-foot level, and will soon make connection with the Mahala workings.—M. O'Connell is working the Maine group of seven claims, on the Mosquito range, and has uncovered a vein that assays 71 ounces silver, 3% copper, 7% lead and $8 in gold. In one of the shafts the vein is 20 feet wide.—The Coronado has a small force of men developing the 550-foot level and is making regular ship-

Prominent Achievements in Metallurgy.

Of the achievements in metallurgy which have either been actually effected or are in immediate prospect Professor Sir W. Roberts-Austen recently gave the following collective statement in his presidential address to the Iron and Steel Institute of Great Britain. There are, he said, blast furnaces which will produce 690 tons of pig iron in twenty-four hours, with a consumption of little over 15 4 cwt. of coke per ton of iron, and the gases of blast furnaces are used not only as sources of heat, but directly in gas engines. There are Bessemer converters which can hold 50 tons of metal, and open-hearth furnaces which will also take 50 tons, while 100-ton furnaces are projected. The open-hearth furnaces are fed with one ton of material in a minute, by the aid of a large spoon worked by an electro-motor. There are gigantic "mixers," capable of holding 200 tons of pig iron, in which, moreover, a certain amount of preliminary purification is effected. Steel plates are rolled of over 300 feet in area and 2 inches thick, and there are girders which justify the belief of Sir Benjamin Baker, that a bridge connecting England and France could be built over the Channel in half-mile spans. There are ship-plates which buckle up during a collision, but remain water-tight. There are steel armor-piercing shot which will penetrate a thickness of steel equivalent to over 37 inches of wrought iron. The points of the shot remain intact, although the striking velocities are nearly 2800 feet a second. There are wires which sustain a load of 170 tons per square inch without fracture. Hadfield, whose labors he hoped to see continued far into the twentieth century, has given us manganese-steel that will not soften by annealing; while Guillaume has studied the properties of certain nickel-steels that will not expand by heat, and others that contract when heated and expand when cooled. Nickel, chromium, titanium and tungsten are freely used alloyed with iron, and the use of vanadium, uranium, molybdenum, and even glucinium, is suggested. Huge ingots are placed in soaking pits and forged direct by 120-ton hammers, or pressed into shape by 14,000-ton presses, and there are steel castings for parts of ships that weigh over thirty-five tons. —Cassier's Magazine for September.

Electrolytic Separation of Cadmium From Iron.

A method for separating these two metals in slightly acid solutions is described in the *Zeitscrift fur Elektrochemie*. As a cyanide solution gives the best deposits of cadmium, certain experiments have been made with the idea of finding out whether such a solution could not be used for the electrolytic separation of iron from cadmium. When an excess of cyanide of potassium is added to a solution of a ferrous salt, a soluble ferrocyanide of potassium is formed. With solutions of ferric salts, hydrated peroxide of iron is produced, and only a very small proportion of iron passes into the cyanide solution. The method proposed is based on the non-electrolytic decomposition of the soluble ferrocyanide of potassium. The mixed salts of iron and cadmium are dissolved in 100 c. c. of water very slightly acidulated with a few drops of dilute sulphuric acid; to this is added two or three grammes of pure cyanide of potassium, and the whole heated until the solution becomes perfectly clear. If this clarification requires too long a time, a few drops of caustic potash may be added. The solution is then diluted to 200–250 c. c., and, after cooling, electrolyzed with a current of 0.05 to 0.010 ampere per square decimeter. The deposit of cadmium is perfectly coherent. If the solution contains but a very small quantity of iron, the floating hydrated peroxide may be neglected; but if, on the contrary, the iron is present in any considerable proportion, it becomes necessary to reduce this ferric salt to the ferrous state by means of a sulphurous acid; to effect this it suffices to add to the acid solution a small quantity of sulphite of soda, and heat for a short time.

Output of Iron Mines.

A prominent iron ore miner says the Lake Superior region will ship 16,000,000 tons of iron ore this season. His estimate for the mines tributary to Duluth–Superior is 7,500,000 tons. The local furnaces, such as those at New Duluth, Ashland and Escanaba, will probably receive some ore during winter, but Pittsburg and Chicago will be supplied during the season of navigation.

The ore shipments from the Lake Superior region will be divided as follows:

Vermilion and Mesaba, 7,500,000 tons; Gogebic range, 2,500,000; Marquette range, 3,000,000; Memoninee range, 2,500,000.

Shipments from the Lake Superior region last season were about 13,600,000 tons. The Minnesota ranges and the Gogebic range are the ones that will provide the increased ore tonnage this year. Practically all of it will be from the Minnesota ranges. There will be an increase of from 1,900,000 to 2,000,000 tons from the entire Lake Superior district, and the Minnesota ranges will furnish about 1,400,000 tons of the increased shipment. The Marquette and Menominee ranges will just about hold their own this year as to output and shipment. The Gogebic will show a fair increase, but Minnesota is the bulwark of the iron ore consumers this year with their great demands.

The Vermilion range, which last year shipped 1,200,000 tons, will this year ship 1,800,000 tons. The Iron Range road will handle 4,000,000 tons this year; the Mesabe road 2,500,000 to 3,000,000 tons, and the Eastern about 1,000,000 tons. Shipping over the Eastern will become heavier after the Sauntry mine begins operating and the road is extended to it.

Next year there will be the same demand as this year for ore, and will probably be greater. But the mines will be in better shape to produce the ore, and the transportation facilities will also be increased. There will be more boats and more ore cars to meet the emergencies of heavy shipping, and the whole scheme of production and transportation of, say, 16,000,000 tons of ore, will be more easily accomplished than this year. Prices for ore will certainly be better than those at which the bulk of ore was sold this season. The big sales were made before the boom in iron and steel commenced.

Ishpeming *Iron Ore* quotes Joseph Sellwood as predicting that the State of Minnesota would send out 8,000,000 tons of ore this season, and thought the entire region would furnish about 16,000,000. The big mines are not always going to hold out. The constant drain at the present big volume makes serious inroads. There are many worked-out properties on the older ranges, and some of the new fields are already feeling the effects of big shipments.

A DELICATE instrument, designed by Horace Darwin, will indicate slow tilts and pulsations of the earth's crust of less than one three-hundredths of a second, or an angle less than 1 inch in 1000 miles. It consists of a circular mirror suspended from brackets by two wires of very unequal length. Slight tilting of the upright causes exaggerated motion of the mirror. The spot of reflected light will vary ½-inch when a finger is laid on the support of the apparatus.

THE wavelike appearance seen on the faces of some sandstones and shaley rocks when broken from their beds is due to either the rippling of water or the action of the wind. The marks thus made have been preserved in the rocks by subsidence of the formation beneath the waters and subsequent deposition of other material upon the bottom of the lake or lagoon. The process may be seen in operation on the shores of a low, marshy shore or on the heaps of drifting sand along the shores of some lakes and the sea.

The Assay of Foreign Lead Ore.

An important decision regulating the sale of foreign lead ores was handed down recently by Judge Hanford of the Federal Court of the State of Washington, in the case of the Puget Sound Reduction Works, operating the Everett Smelter, on appeal from a decision of the United States Board of Customs Appraisers in New York City.

Judge Hanford holds that, under the United States laws, what is known as the "fire" assay shall be used to determine the amount of dutiable lead in imported ores, and gives the smelter company judgment against the United States for the amount of excess duties paid on ores shipped to it under the ruling of the Washington officials that the "wet" method should be used in assaying such ores.

Under the new ruling, the Government will be compelled to change its system of assaying imported ores for the purpose of obtaining values on which to figure duties. In the past the official system has been the "wet" or chemical process. It is contended and generally acknowledged that this process yields about 2% more lead than the fire system. The smelter people fought the case and won on the theory that the commercial method is the fire assay. The decision settles the question as to whether the wet or the fire assay is the commercial method by declaring that the evidence is satisfactory and convincing in favor of the latter.

Judge Hanford had the case under advisement and handed down a written opinion. Reviewing the evidence, he says, in part:

"It would require a very strained construction of the law to find that Congress, after having in 1894, and again in 1895, enacted statutes requiring the sampling and assaying of ores, for the purpose of collecting duties thereon, to be according to commercial methods, and without having expressly repealed the law of 1896, could have intended in the law of 1897 to continue the same policy as regards the methods of sampling and yet departed from that method for the purpose of assaying.

"It is my opinion that the Secretary of the Treasury is required, by the positive provision of the Acts of Congress above referred to, to prescribe regulations for the assaying of lead ores by the commercial method, is a question of fact, for the decision of which resort must be had to evidence.

"In this case the evidence is all one way and it is in all respects satisfactory and convincing. From it I find that the commercial method of ascertaining the quantity of lead contained in imported ores is the fire process, and any other method of assaying does not meet the requirements of the law."

AN old wagon bridge which has spanned the Wabash river, near Clinton, Ind., for half a century has been removed by aid of the electric current. The county bought the piers, the principal owner agreeing to remove the superstructure to make way for a new bridge. Efforts were made to burn the bridge, but it was found that this would injure the piers, so the sills were wired and electricity applied. In nine hours the pile toppled into the river, leaving the foundations unhurt. The current had the effect of cutting all the sills simultaneously as with so many saws.—Electricity.

The oldest iron steamship in the world is the United States steamer Michigan. The vessel was constructed at Pittsburg, Pa., in 1841–43; the parts were transferred to Erie, put together, and launched on December 5, 1843. The original machinery, with the exception of the boilers, is still in her and in good condition. The vessel is an iron paddle-wheel steamer of 685 tons displacement; length of keel, 156 feet 4 inches; length between perpendiculars, 162 feet 6 inches; breadth of beam, 27 feet; depth of hold, 12 feet 5½ inches.

Rare Brazilian Sand Used for Incandescent Mantels.

The monazite or Prado sand, which is used in the manufacture of the Auer incandescent mantels, says the London *Electrical Review*, is found at Bahia, Porto Seguro, and in small quantities in Matto Grosso, Brazil. In the first two places the sand is found close to the shore and is derived from the decomposition of the neighboring gneiss. It is of a dark yellow color, like gold, and very heavy. The following is an average analysis:

	Per Cent.
Aluminum	3
Cerium	62 to 70
Iron	2½
Lanthanum	2½
Thorium	1½ to 3½
Yttrium	1 to 2

Cerium is an extremely rare metal, hitherto found only in Sweden. Its color is a whitish-green, and it has considerable metallic luster. Its specific gravity is almost equal to platinum. Mixed with copper and zinc, an artificial gold is produced, having the same luster and weight as real gold.

Thorium is of a gray color, and when burned in air or oxygen is converted into an oxide. The metal combines energetically with chlorine, sulphur and phosphorus and dissolves in hydrochloric acid, liberating hydrogen in the process. As may be supposed, there has been a considerable run on these valuable sands since they were discovered, and it is expected that the value of this current year's exports will be more than double what it was last year.

Thirty-three Miles of Aluminum Cable.

The Hartford Electric Light Co. of Hartford, Conn., has ordered thirty-three miles of aluminum cable. The company is building a concrete dam in the Farmington river, at Tariffville, Conn., eleven miles from Hartford. From this waterfall it will realize 2300 H. P., which will operate two 1000 H. P. generators, giving 10,000 volts. This current is to be transmitted over aluminum cables to the company's power station in the city of Hartford. There will be three cables for transmitting the current, strung in the form of a triangle on double crossarms and double insulators. The wires will be left bare and will run to within a mile of the city limits, when the current will be reduced to 2400 volts, at which voltage it will run to the company's city generating station, where the current will be transformed to a lower voltage for power and lighting purposes.

Each cable has seven strands, and each strand is made up of seven wires of No. 11 Brown & Sharpe gauge. The complete cable is about 1 inch in diameter, and has a conductivity equal to No. 0000 copper wire. Aluminum is to be used in the high-pressure transmission line only, and by utilizing the light metal instead of copper the company estimates that, with present prices for copper, it will save $3500. —Electricity.

THERE is no data available which would furnish anything like a reliable estimate of the extent of the underground workings of the Leadville, Colo., mines, but the sum total must be enormous. For twenty years the hills have been honeycombed with underground drifts, and the work is still progressing. For the past two or three years from five to six miles of new work have been done in the Ibex mine, and there are now upwards of forty miles of workings in that property alone. There are about twelve miles of workings in the Chrysolite, and at least as much in the R. E. Lee. The Carbonate hill mines have honeycombed that hill very thoroughly, while Iron hill has been burrowed through to an enormous extent. It is safe to say that if all the drifts, levels, winzes, upraises and shafts in Lake county were represented by a continuous tunnel, it would represent an underground passageway of over 1500 miles. There are some calculators who can figure out that there are at least 2000 miles of workings.

Mining Summary.

ALASKA.

The last monthly reports of the Alaska-Mexican and Alaska-United mines show results as follows: The former crushed 14,666 tons ore, valued at $19,679, and turned out 299 tons sulphurets, valued at $10,201. The ore averaged $2 20 per ton. The gross earnings were $32,178 and the working expenses $19,089. The latter mine crushed 24,134 tons, valued at $35,725, and yielded 645 tons sulphurets, valued at $20,163. The ore averaged $2.52 per ton. The gross earnings were $58,806. One of the mills, dependent $60,765 and the working expenses were upon water power, had to hang up some of its stamps five days during the month because of the short supply.

Juneau *Miner*: The following are the values of Alaskan and British Yukon gold:

	Per oz.
Little Manook, American	$19 50
Anvil, Cape Nome	18 50
Ophir, Golo in Bay	18 50
Hunker, Klondike	17 00
Pine, Atlin	16 75
Wright, Atlin	16 75
Dominion, Klondike	16 75
American, Eagle City	16 75
Porcupine, American	16 75
Chicken, American Yukon	16 75
Bonanza, Klondike	16 30
El Dorado, Klondike	15 50

El Dorado carries the poorest quality of Yukon gold, and Little Manook the richest. The highest assay returns from Yukon gold were from gold taken from No. 8, Little Manook, owned by former Governor J. H. McGraw and Gen. E. M. Carr. It ran $19.63 per ounce. The American Cape Nome is high grade. El Dorado gold has run as low as $15 per ounce. As high as $17.09 per ounce has been obtained from discovery claim on the American Porcupine Creek.

ARIZONA.

MOJAVE COUNTY.

The 20-stamp mill at the Sheep Trail mines, near the Colorado river, is running.

The C. O. D. mine on Stockton hill is again working. The old dumps are to be milled and concentrated.

W. J. Shick of New York has commenced work on a large hydraulic plant in the Ehrenburg district for the purpose of working the Trego placers. Water will be pumped from the Colorado river, five miles, and the plant will handle 2000 yards of gravel per day.

YAVAPAI COUNTY.

(Special Correspondence).—R. A. Thomas, Pres. Black Hills Copper Co., has arrived at Jerome from Los Angeles, for the purpose of initiating the work of the newest Jerome company. All matters pertaining to the organization are reported satisfactorily consummated.

Several boarding houses and bunk houses have been put up at the Iron King and Copper Chief properties, which are as yet in the hands of the Chinese. At the Copper Chief nothing new is reported. The Iron King is working in the lower tunnel. The surveyors have completed the new pipe line from Allen's springs and within thirty days will begin laying pipe.

Jerome, Sept. 9th, '99.

CALIFORNIA.

Amador.

The Oneida mine, between Jackson and Sutter Creek, makes 400,000 gallons of water daily.

S. R. Porter is making good headway in the shaft of the Mutual mine, south of Amador City. The shaft is in a slate formation full of quartz and sulphurets. This is the newest large enterprise in Amador.

C. E. Purington, formerly superintendent of the Gover mine, near Amador City, has bought the Loyal Lead, near Drytown.

Amador *Ledger*: Bryson & Worthing, of the Globe M. & M. Co., have a bond on the C. Kretcher property, south of the Bay State mine. It was opened many years ago and a mill test returned $4.65 per ton in free gold. A tunnel cut the Bay State ledge and also the Kretcher ledge, though the latter was not noticed. A drift south shows that they come together 25 feet from the original tunnel where the ledge is 12 feet thick of good value in free gold with 4% sulphurets. They will sink a vertical shaft.——At 300 feet in the old shaft, a crosscut was driven to the Kretcher vein, from which valuable ore was milled. At the 750-foot level crosscutting to the Kretcher ledge is in progress, now in 340 feet.

Butte.

N. S. Trowbridge, at the Robinson mines, is putting up a new hoist building. A boiler and a double-cylinder hoist for sinking 1000 feet have been added, and power drills will be used. The shaft is down 100 feet below the creek level. There are 1400 feet of tunnels on the ledge above the collar of the shaft. The 20-stamp mill has been rebuilt and ten stamps will run.

Calaveras.

It is reported that the Lucas mine, on the Mokelumne river near Big Bar bridge, has been sold to the owners of the Tomboy mine in Colorado, Posey & Co., for $20,000. The purchase price was paid down. The new owners express a purpose to expend large sums of money on the property.

F. F. Thomas, president and manager of the Gwin mine, accompanied by J. McSorley, visited North Branch recently and examined the Hudson, Mester and Jackson mines, near Central Hill.

The Hudson vein lies at a low angle and a vertical shaft was sunk through it by early operators. Development work has been done on the mines lately.

Jackson *Dispatch*: High grade ore in the Demarest mine, near Fourth Crossing, is coming from the 400-foot level.——At the Barstow mine, near Glencoe, a new hoist and mill are being erected. The mine was recently sold in England.

San Andreas *Prospect*: At the Lightner mine in Angels, Supt. H. G. Murray will sink the main shaft now down 450 feet to 650 feet. The 40-stamp mill is crushing 208 tons of ore in twenty-four hours.

Angels *Echo*: The new hoisting machinery is in position at the Harris mine, a mile south of Angels, and the gallows frame is completed.

Inyo.

It is reported that a Vermont marble company is negotiating for the Lindsey marble quarries east of Antelope.

The Anthony group of mines in the Panamint range is reported sold for $45,000.

Kern.

Three shifts are rushing development work at the Butte mine at Randsburg.

Bullion returns on 1800 tons of ore crushed at the Red Dog mill near Randsburg amounted to $41,367.

Randsburg *Miner*: From a run of thirty-seven tons of ore the Kinyon mine owners received $11,000, and from twenty tons of second class ore milled they received $1000. One hundred and forty tons of ore taken from the dump averaged $8 a ton.——The Yellow Aster Co. has eleven men working at the wells drifting. They have encountered another good flow of water. At the mine 152 men are employed—137 in the mine and twenty at the mill. The payroll runs over $13,000 per month.

Marin.

Near Bolinas, oil deposits are reported on the outskirts of the town. J. D. Bradbury of San Jose has bonded several ranches and has ordered a plant and will commence sinking wells. Oil was first discovered near Bolinas several years ago by R. Coltingham. On the beach, among the rocks, natural gas is fonnd. When the tide is out, on Duxbury Reef, the gas rushes out of the rocks, when lighted it will burn until extinguished by the tide. Ledges of asphaltum have been discovered on the beach.

Nevada.

The shaft of the Bismarck & Gladstone mine, near Selby Flat, is to be sunk an additional 100 feet.

Grass Valley *Union*: Steam was started on the old Union Hill mine on the 8th inst. for the first time in many years. The pumps are in operation. Sinking will be begun and old drifts cleaned out.

Grass Valley *Union*: Supt. Brockington reports work progressing favorably at the Omaha, Homeward Bound and Lone Jack mines under his direction. Sinking was commenced at the Omaha and drifts are being run in both directions at the bottom.

Placer.

The Jupiter mine, near Iowa Hill, cleaned up $2200 for August, the result from drifting.

At the Sailor mine, in Sailor canyon, where a large amount of money has been expended in search of a gravel channel, a new tunnel has been started, on the advice of N. A. Harris, 400 feet higher than the old workings. It is thought the channel will be found in 350 feet.

Nevada City *Herald*: A carload of rich copper ore was shipped from Sheridan to the smelter last week.——Prospectors on Bear river are finding rich ground at 30 to 50 feet depth with augers.

Plumas.

Oroville *Register*: Steam-power drills are to be used in the Robinson mine in Granite basin, and a new hoist is being put up. A new water wheel has been put in, which will give more power than the one formerly in use. R. C. Robinson has two shifts working and expects to strike ore this week. Men are building 2300 feet of flume to carry 250 inches of water, which will be used to run an 8-inch hydraulic elevator.——San Jose capitalists are to open what is known as the Elizabethtown channel mine.

San Diego.

Miners are investigating the gold-bearing veins near Campo, in Laguna mountains.

Ex-Receiver C. W. Pauly of San Diego has petitioned the court for privilege to work the tailings of the Golden Cross mill at Hedges. There is a large amount of this material accumulated and it all contains value in gold.

San Joaquin.

The Golden Gate Oil Producing Co. has been incorporated at Stockton. W. R. Thomas, D. O. Castle, S. E. Lotta, W. J. Rhodes and S. M. Spurrier. Capital stock, $100,000.

Santa Barbara.

The St. Valentine M. Co. has been incorporated at Santa Barbara. W. Easland, G. F. Treuwith, J. H. Burson, A. C. Grant and C. A. Stork. Capital stock, $100,000.

Santa Clara.

The Gay Quarry Co. has been incorporated at San Jose. W. A. Porter, C. Wehner, G. Lion, J. W. Rea, A. C. Darby, A. Greeninger and T. W. Hobson, San Jose. Capital stock, $50,000.

Shasta.

(Special Correspondence).—The Coronado Copper M. Co. of San Francisco is developing a large area of territory twenty-six miles southwest of Redding, in the neighborhood of the Bully Choop mine. The company owns 400 acres. J. Blumenthal is president and R. Mohr secretary. A contract was recently let to run 400 feet of tunnel, which is calculated to cut the ore body at a depth of 230 feet. A 60-foot shaft opened a vein which was crosscut 18 feet without finding the walls. The contract price is $5 per foot.

Basset & Welch are running a new tunnel in the Eureka mine near Shasta. They found a third ore body on this property, which assays $22 a ton.

Behrns & Lievasay are working seven men on the Oro Fino mine near Shasta. This mine has had many operators in the past few years. The present company has found the ore body so long sought. The values are from fair to high grade.

The recent transfer of copper properties at Furnaceville and Copper City has stimulated prospecting in those sections and almost every available claim has been located.

In the neighborhood of Kennet about sixty claims have been relocated (jumped) since the announcement of the news that the last Legislature did not repeal the Act of '97.

Redding, Sept. 13th, '99.

Experiments are to be made with the ore of the Yellow Rose of Texas. The gold-bearing material is talc and clay and does not crush readily under stamps.

That there has been unusual interest in mining in this county the past year is shown by the number of locations filed for record during the past twelve months as compared with the number during the twelve months preceding. From Sept. 7, 1897, to Sept. 7, 1898, 1184 locations were filed with the County Recorder. From Sept. 7, 1898, to Sept. 7, 1899, the number was 1735—an increase of 551.

Shasta *Courier*: A number of men employed at the Mount Shasta mine have been laid off and sinking on the ledges is in progress to open ore deposits on lower levels.——At the Old Bunker Hill mine development is in progress. Rich rock, carrying tellurium and free gold, has recently been discovered in a defined ledge. The mine is two miles south of Shasta and is owned by Mrs. J. Loag of New York, J. V. Scott and others.

Sierra.

Downieville *Messenger*: Articles of incorporation of the Twin Eagle M. Co. have been filed with the County Clerk. The capital stock is $50,000. The directors are J. U. Hastings, J. S. Wilbur, F. S. Gould, E. McGary, Jr., and J. McGary. The company is preparing to operate the Gray Eagle mines on Kanaka ravine. A mill recently purchased in Nevada county is on the ground, and construction work commenced.——J. S. Wilber, Supt. Gray Eagle mine, near Gold Point, is at the mine and has commenced grading for the mill.

Siskiyou.

The Greenhorn Blue Gravel mine has been purchased by A. & L. J. Wetzel, J. E. Harmon and W. R. Ridenour, who intend sinking a new shaft and adding apparatus for working on a more extensive scale. John Garvey will continue as foreman.

The group of quartz mines on Squaw creek, a tributary of Willow creek, in the Gazelle district, promises to turn out well. The mines show a ledge 98 feet wide, and have been bonded to Dr. G. W. Dwinnell, of Montague, for $45,000, the agreement being that quartz yielding $30 a ton or more be shipped to Keswick and lower grade ore stacked until a mill is put up.

A four-mile ditch is to be dug from Buckhorn creek, a tributary of Horse creek, on Klamath river, to the Poverty Point and Yankee placer mines opposite Oak Bar.

W. A. Bantz started up the mill on the Little Tiger mine at Greenhorn last week, but has shut down to make alterations in machinery.

Mr. Rader, who bought out the Hunter-Johnson quartz mine at Horse creek, on Klamath river, has been finding rich prospects. The sulphurets contain gold, but have to be sent to the Selby works.

Yreka *Journal*: The company working the mine at Greenhorn on the Nehrbass place, adjoining the Blue Gravel mine, are down 130 feet, which indicates that it is in a deep ancient channel.——Work is to be started again on the cinnabar mine at the head of west fork of Beaver creek, by the Siskiyou Con. Q. M. Co. Mr. Newcomb has been at the mine lately, making arrangements for starting with fifteen men.——The ledge at the Golden Star or Spencer mine, on Humbug creek, is rich but small.——G. W. Foote, working the Merrimac mine on Humbug, has a rich ledge.

Tuolumne.

Sonora *Independent*: J. Meighan has men grading for the 20-stamp mill on the Mt. Jefferson mine, at Groveland.——A new station in the Accident mine of Big Oak Flat has been cut and drifts driven. The ledge is 21 feet wide. The property is managed by J. Meighan.——Rich ore is being taken from the Republican mine at Jacksonville.——Byrne & Herndon have bought the Ophir mine, near Big Oak Flat, from Mr. King, and will erect a mill.——C. Hall has returned from Placer county and has resumed work on the Golden Eagle pocket mine in Big Oak Flat.——At the Pauper's Dream, formerly the Accident, in Big Oak Flat, they are down 260 feet in good ore and are drifting on the 100-foot level in $20-rock.——The Mississippi mine, at the lower end of Big Oak Flat, has started up again.——At the Nonpareil shaft, near Deer Flat, ore bins are being built. The shaft is down 80 feet and sinking in good ore.

Sonora *Union-Democrat*: Forty-five men are constructing a dam on the Stanislaus river, four miles below Robinson's Ferry. When completed an electric plant is to be put in and power sold. The enterprise is owned by C. D. Lane & Co.——At the Bown, near Robinson's Ferry, ten men are drifting on the cross-vein at the 300 and 400 levels. The quartz at these points has a width of 3 feet of ore.——Work on the Alameda, near Rawhide, which was to have been resumed, has been indefinitely postponed. The entire force was laid off Saturday.——Three shifts are making 15 feet a week in the Arbona shaft at Tuttletown, in hard rock. No crosscutting or drifting will be done until 600 feet is reached.——The Norwegian, near Tuttletown, has closed down on account of lack of water, and will not resume until the first of the year.

COLORADO.

BOULDER COUNTY.

Staples & Eddy have attached the Ward pyritic smelter, claiming $580 for work, driving the tunnel on the St. Louis mine, which is under bond and lease to the smelter company.——The upraise in the San Blas, connecting the lower workings with the surface, will be completed next week. A body of ore has been opened in the upraise and shipments will be made.——The B. & M. is driving the 190, 400 and 600-foot levels west, and is shipping three carloads of smelting ore per week.——The leasers on the Ni Wot have two carloads of concentrates ready for shipment.—— The Ward-Rose will soon be in operation on development work. J. Muehlbronner of Pittsburg, one of the stockholders, will superintend the work.

CHAFFEE COUNTY.

(Special Correspondence).—The D. & R. G. R. R. main line runs within four miles of Turret and a branch runs to the Calumet iron mine through the camp, giving good railroad facilities. Buena Vista has a smelter eighteen miles distant and Salida is to have a 200-ton smelter fourteen miles from Turret. Assays of the camp range from a trace to $2500 in gold per ton, and it is nothing unusual to get assays of from 10 to 20 ounces in gold per ton. The formation is graphic granite; the veins are hematite and jasper, porphyry in most cases running with them, the dykes being 3 to 30 feet in width. In depth copper appears in nearly all the veins and occurs in a variety of forms. The veins are of good width. It is two years since the first location was made here.

The Gold Bug has the deepest shaft in the district down 200 feet and is sinking to 300 feet. Shipments from this property range in value from $29 to $34 per ton in gold; it also carries copper and silver. The vein at the 100-foot level is 31 feet wide. A crosscut at the 200-foot station is being run to determine the width at that depth.

At the Holdridge, which is 75 feet deep, the smelter returns show the ore to run $92 per ton. Work is being pushed throughout the camp. The altitude is 9000 to 10,500 feet.

Turrett, Sept. 9th, '99.

The plans have been completed for a 60-ton smelter to be erected by the Salida Mining & Smelting Co.

Cree camp, near Monarch, is about to commence steady shipments. The Clinton mine has ore that runs $2 in gold, 64 ounces silver, and 20% lead. More than 750 feet of development has been done.

A new camp called Dawson has been formed near Cree camp, and ore taken from the surface assays from $180 to $200 to the ton in gold. A large number of claims have been located, and work is in progress.

CLEAR CREEK COUNTY.

The Newhouse tunnel is to resume work.

The Stevens mine recently made a shipment of ore that carried 60% lead, 30 ounces in silver, and $2 in gold to the ton.

The Johnson mine, in Argentine, recently had a mill run of ore that ran 387 ounces silver and 19% lead, worth $230 per ton.

Ore has been found in the Independence that runs 2370 ounces in silver.

F. W. Isham of Denver has a lease upon half of the dump of the Mendota mine at Silver Plume, upon royalties aggregating 20%. He operated in the interests of Denver mining men. This dump is one of the characteristic sights of Silver Plume, containing 80,000 tons of rock, carrying fair values in zinc, lead, gold and silver. The work of reducing the dump has been begun in the Dives-Pelican mill.

GUNNISON COUNTY.

The Hercules and Ajax properties are being worked above the tunnel. A mill run of concentrating ore was made last week. T. Nichols, of Denver, is opening the Denver City, on Sheep mountain, Crystal district. Copper ore is being taken out and shipment will be made. R. J. Walter and F. Kratzer are owners with Mr. Nichols.——O. Allen has made a proposition to the mine owners at Snow Mass, Crystal district, to put in a concentrating plant for the treatment of the mill dirt of the copper prospects in the vicinity.——A strike of rich copper ore has been made in the lower tunnel of the Burt mine. Native copper is found in the gangue.——The Scofield mill is now operating on ore from the Whopper.

LAKE COUNTY.

At the annual meeting of the Fanny Rawlings M. Co., owners of the Fanny Rawlings claim, on Breece hill, in the gold belt, held at Colorado Springs, it was determined to purchase a $10,000 plant of machinery and to deepen the shaft 200 feet. The mine commenced shipping in November, 1898, and $200,000 was the gross receipts up to April 1, 1899. Two dividends from royalties amounting to $20,000 have been paid this year. The lease is held by Taylor & Copeland of Aspen. The mine is shipping twenty-five tons daily of gold-copper ore to the Bi-Metallic. This property had remained undeveloped since its location, twenty years ago. Manager J. F. Walsh has made a study of the occurrence of the Breece hill ore channels and developed the Fanny Rawlings.

Colorado zinc ores are of good value, but not as easy to reduce as the Missouri ore on account of the iron it contains. One large smelter works has a contract for several thousand tons of 50% zinc at $30 per ton. The Veille-Montague Co. of Antwerp, Belgium, has made a flat contract for 5,000 tons of Colorado zinc at $8 per ton, F. O. B. Jacobsen & Co. of New York City, zinc brokers, are making purchases in this market and have wired to increase shipments. The Louisville will increase its zinc output as the stopes are opened.

The Greenback is drifting on the 1100-foot level, and will soon make connection with the Mahala workings.——M. O'Connell is working the Maine group of seven claims, on the Mosquito range, and has uncovered a vein that assays 71 ounces silver, 3% copper, 7% lead and $8 in gold. In one of the shafts the vein is 20 feet wide.——The Coronado has a small force of men developing the 550-foot level and is making regular ship-

ments of twenty-five tons of iron per day.—Leadville has sent 150 men to work in the Cœur d'Alene district of Idaho.—The old Homestake mine, west of Leadville, which was a heavy producer in the early days, but damaged by snowslides one year ago, is again being put in shape for production.—The Fortune mine has shipped steadily throughout the smelter strike. The company is working a body of lead ore 12 feet wide carrying gold, silver and copper.

Leadville *Miner*: The A. Y. and Minnie mines and mills, worked under lease by Newton & Douglas, are making an output of 150 tons daily. The mill is the best conducted and the best dividend earner in the history of the camp. The concentrates run twelve to thirteen ounces silver and 30% lead.

LARIMER COUNTY.

It is reported that valuable mineral claims have been discovered near Gray Rock in the Poudre canyon, twenty-five miles west of Fort Collins. The ore carries gold and silver in large quantities.

OURAY COUNTY.

At Ouray on the 6th inst., a drilling contest resulted in McKenzie and partner of Leadville winning the champion double-handed drilling match, scoring 37⅞ inches.

PITKIN COUNTY.

Aspen *Sun*: Shipments are to begin from the Birthday mine, ten miles up Maroon creek from Aspen, formerly the Sunset mine. The property was never patented, though developed extensively. P. Palmer and U. G. Parnell made the relocation and began work. Assays taken from ore thrown over the dump by former operators show: Silver, 25 ounces; lead, 20%; gold, a trace to $8; copper, 2%. The ore carries 12% in zinc. Although the lead is high, the silver value is not with the lead.

SAN JUAN COUNTY.

Silverton *Miner*: Dr. Pascoe is about to place a 10 H. P. gasoline hoist on the 90-foot shaft of his Prodigal Son claim in Porcupine gulch, Cement creek. Assays from a 1⅝-foot streak of solid sulphide of iron-copper ore from the shaft returned $40 per ton.—An 8-ton lot of ore recently shipped from the San Juan Queen on Mastadon gulch, sampled $156 a ton. W. Fisher and H. Sherman own the mine which is worked by leasers.—The Commonwealth Exploration M. & M. Co. is operating the Zuni, at Silverton. A 1,200-foot crosscut tunnel to the lead 500 feet below the present workings is to be started.—E. H. Briggs et al. are again working their Turtle Dove, on Galena mountain. There is a body of high grade zinc ore in the mine.

SUMMIT COUNTY.

The Cashier G. M. & M. Co. has begun the construction of an amalgamating and concentrating mill. The preliminary work has been started.—H. Lee is groundsluicing south of Breckenridge. A test of 4 cubic yards of gravel yielded a return of $2 per yard.—The Jessie mine, operated under bond and lease by the North American Gold Dredging Co., has been cleared out, and shows good shipping ore and a body of milling dirt. The 40-stamp mill is being overhauled and repaired.—At the Mountain Pride mine the new mill is near completion and the new shaft has been unwatered and a force put at work driving the 80-foot level to a connection with the old workings.—The Ella recently completed the shipment of seventy-five tons of lead ore carrying a small amount of gold and silver.

TELLER COUNTY.

Lessee W. O. Dunham, operating a block of Stratton's Longfellow property, will resume shipments. The new shaft has a depth of 130 feet, at which point the shoot was cut on its dip. A station has been cut at the bottom of the shaft, and work on the ore is started. New ore bins have been erected.

In the Carlson lease on the Morning Glory No. 4 of the Work, two men are daily breaking ten tons of ore. The pay streak is more than 6 feet wide, and will average two ounces. The shoot is still strong.

The Mollie Dwyre, a patented claim of seven acres on Gold hill adjoining the Pointer, has been sold to R. C. Bogy and associates of Denver for $25,000. It is the intention of the new owners to organize a company and develop the ground.

At the annual meeting of the National M. T. & L. Co. held last week the directors decided to install a three-drill compressor on the Red Bird claim. On the 260-foot level the vein has been opened 160 feet. The ore averages 3 to 4 feet, and carries values from $50 to $70.

The Burris & Sexton lease on the north end of the Last Dollar mine of Bull hill is down 160 feet, and a vein encountered that assays $14 to the ton.

Purcell, Limbach & Welch, leasing on the Monument, are shipping from two shafts. The two shafts are 30 and 40 feet deep, and sinking continues in both of them. Sub-lessees Rhodine & Clark have seventeen-ounce ore, and will soon be shipping. A switch is being run to the Monument by the Midland Terminal road.

A new vein has been encountered in the Clemmons lease on the Dante, on Bull hill. The vein was unknown to the lessees. The vein shows 15 inches of ore, which assays three to eight ounces. The new vein was cut in a crosscut 12 feet from the Clemmons vein. The vein is 3 feet wide, and in it there is a streak of talc that runs as high as thirty ounces. A new plant of machinery has been put in. Four air drills will work in the sixth level—two in ore and two in development.

It is reported that a strike has been made on the Something Good, on Raven hill, and that 4 feet of pay ore has been found.

A. C. Hutchinson and associates of Denver have sold the Lucky Boy's Friend and the E. & H. lodes to A. P. Mackey of Denver.

The Logan, on Bull hill, is down 1180 feet. In the fifth level a large body of ore was encountered in the drift. Ore is now in all the levels from the first to the seventh. From the eighth to the eleventh levels only the stations have been cut. There are over 5000 feet of drift.

The Thompson mine, on Gibbons hill, was sold last week to the Colorado Ore Reduction Co., owner of the Arequa mill. This mine adjoins the Elkton, and has been a producer of medium grade ore. Ore was first opened in it last year by G. M. Weeks, of Chicago, who secured the property. Since that time it has been a heavy shipper. The new owner will sink the shaft 200 feet from its present depth of 520 feet. This purchase is to make the mill in Arequa gulch independent of custom ore. The company has five leases in the camp, four of which are shippers. The Thompson has been outputting sixty tons a day, which is to be increased to 100 tons. A tramway is to be built from the mine to the mill.

At a recent meeting of the Jack Pot Co. it was shown that the Creston Gold Mining Co., lessee of the south 600 feet of the Jack Pot claim, had encroached upon the company's territory to the extent of some 63 feet, from which they had extracted ore to the amount of $36,000. A demand for restitution of the $36,000 from the Creston Co. will be made, minus the cost of extracting the ore and minus the royalties paid on it.

The Old Colony Co., the Cripple Creek Railway Co. and the Finance Co. have each been incorporated and capitalized at $1,000,000. The incorporators of each are practically the same. These incorporations are connected with the plans of G. H. Proctor of New York, who two years ago attempted to float the Pike's Peak Tunnel & Railway Co., which proposed to bore through the range with a railway tunnel, which would end 4000 feet below the town of Victor, and have two branches encircling the Cripple Creek district, the total distance of the system underground being fifty miles. The present plans of Mr. Proctor are the same as those brought forward a year ago. The Finance Co. proposes to erect a reduction works eighteen miles north of Canyon City. The Old Colony Co. is organized to conduct mining enterprises in the Cripple Creek district, several claims having been secured by Mr. Proctor. The Cripple Creek Railway Co. proposes to build a road from Cripple Creek to Canyon City and from Cripple Creek to Denver. Mr. Proctor has left for New York. He says that bonds of the railway company and the Finance Co. are practically placed, and men are at work securing the right of way and have 8000 acres along the line. P. Morton, vice-president of the Santa Fe system, has been in Cripple Creek and Canyon City to look over the ground. It is reported that the Santa Fe is looking for a route into Cripple Creek. The Finance Co., besides the construction of a hotel and reduction works, proposes to drive the tunnel under Cripple Creek, which initiated Mr. Proctor's operations in this State. The tunnel will extend from Colorado City, El Paso county, to Marigold, this county. Mr. Proctor considers it feasible. The company will commence at the western terminus of the tunnel and reach within a mile of the town of Victor. The reduction works will have a capacity of 500 tons a day, and the cost of the plant is estimated at $500,000. The Finance Co.'s incorporators are G. H. Proctor, M. J. Stair and M. A. Rogers.

The Pike's Peak Power Co., to do business in Fremont, El Paso and Teller counties, has been incorporated with $1,000,000 capital stock by W., H. E. and F. M. Woods.

Denver *Republican*: The Doctor mine is again in bonanza ore, on Raven hill. There is a variance of opinion in regard to the particular shoot from which the mineral is coming. It is asserted that there are two veins—the Jack Pot vein and the Doctor vein. Some claim that the ore from the Creston G. M. Co. is coming from the Jack Pot vein, which, it is asserted, is distinct from the Doctor vein. They also claim that the Doctor vein, with the exception of the deposit from which Cone & Lyman shipped their bonanza ore in the early days of the camp, is barren. Those operating the Doctor mine assert that the Doctor and Jack Pot veins are the same. The mineral now being produced by the two properties is identical. In the meantime the old Doctor mine is again hoisting good mineral, and the lessee and sub-lessees are permitted to continue producing without being stopped or even hindered by litigation.—The Orphan Belle, on Bull hill, is owned by two newly organized companies—the Arrow and the Orphan. A number of lessees are at work; some already are breaking good ore.

IDAHO.

ADA COUNTY.

Idaho *Statesman*: R. J. Anderson states that the tunnel he has been running on the Copper Queen on Badger creek has cut the ledge, and that it has opened a fine body of ore. The walls are granite. The ore is 12 feet wide and is opened at a depth of 90 feet, the tunnel being in 127 feet. Assays gave from $3 up to $180, the average being $37.82. The ore is of different character at different points in the ledge, part of it being hard quartz heavily impregnated with iron pyrites. The ore concentrates readily. Mr. Anderson intends to make further test by concentrating thirty tons. There is a 1-stamp mill at the mine, through which the ore will be run, being concentrated on canvas. At the Sinker creek tunnel an 8-drill compressor will be installed, also a ventilating plant. The plans of the enterprise contemplate the expenditure of $500,000 in the purchase of property and in running the tunnel.—H. W. Dorman reports Willow creek lively. The Checkmate 10-stamp mill is completed, awaiting machinery.—The Leviathan mill and mine are running. The mine has a large body of ore on the 160-foot level. A portion of the ore is being shipped; the balance of the ledge is milled.—N. J. Sorenson recently bought the Richmond mill and is running on ore taken three years ago from the Pinto mine. He is retimbering the mine.—A strike has been made recently on the Shamrock in the old workings.—Mr. Dorman is operating the I X L and Ada. In the latter a body of ore has been opened. The I X L tunnel is in 500 feet. Three eight-hour shifts are to be put on.

IDAHO COUNTY.

(Special Correspondence.)—Hobson's Choice, at Buffalo Hump, was sold to W. S. Norman, F. C. Innes and Mr. Cameron of Spokane, by A. N. Graham, L. Yates, W. H. Palmer and J. C. Moore. The St. Louis, also at Buffalo Hump, was recently sold by Young & Turner to Boston capitalists.

Lewiston, Sept. 9th, '99.

LEMHI COUNTY.

The Black Bird, near Salmon City, has let a contract for a wagon road from the main road to the mines, and October 1st machinery will be installed and active operations begun under Mr. Buckley's supervision. It is the intention to explore the copper-bearing area to depth when concentrating machinery and matting furnaces will be provided.

On Moose creek the Pacific Dredge Co. has a machine in operation and is handling 1,000 cubic yards daily, the gravel averaging fifty cents a yard. Others are employing giants with good results. At the California Bar, Leesburg, a large force is being worked. Estimates place the clean-up for the season at $250,000.

Capt. Singster will operate a dredging machine on his placer and has ordered a dynamo for his quartz mill and will hereafter employ electricity in the extraction of his metal.

MONTANA.

MISSOULA COUNTY.

Two carloads of ore have been shipped from the Last Chance, and one from the U. S., this week. These two properties have furnished all the ore which has ever gone from Saltese, each turning out an occasional carload for six or seven years. They adjoin on Packer creek, four miles northwest from Saltese. The ore is nearly all carbonate, running high in silver, with a little copper and gold and runs from $200 to $300 above freight and smelter charges.

NEVADA.

It is reported that all the companies on the Comstock interested in the new electric power installation have signed the bonus contract, excepting Hale & Norcross. The bonus is raised by apportionment of a certain percentage to each mine, as follows: Con. California & Virginia, 15%, or $15,000; Sierra Nevada, Union Con., Mexican, Ophir, Best & Belcher, Gould & Curry, Savage, Chollar, Potosi, Crown Point, Belcher and Yellow Jacket, each 7½%, or $7500 each; Hale & Norcross, 5%, or $5000; Confidence, Caledonia and Occidental Con., each 1½%, or $1500 each; Utah Con., Andes, Bullion, Alpha Con., Con. Imperial, Challenge Con., Seg. Belcher, Overman, Alta and Justice, each 1%, or $1000. The total amounts to 124½%, or $124,500. The payment of the bonus will be made in installments as follows: First payment, $5000, upon the signing of the contract; second payment, $20,000, thirty days after the date of execution of the agreement; third payment, $25,000, ninety days after the date of execution of the agreement; fourth payment, $25,000, in 120 days after the date of execution of the agreement; the balance, $25,000, upon the completion of the power plant and successful working of the same.

At the C. & C. shaft, Comstock lode, No. 2 elevator has been removed, repaired and replaced. It is thought more rapid progress will be made. The water stands 34 feet below the 1950 level.

ELKO COUNTY.

(Special Correspondence).—As the result of two weeks run of the 40-stamp mill, with cyanide tailings equipment, on the property of the Dexter G. M. Co. at Tuscarora, a bar of bullion of the value of $14,560 and auro-cyanides valued at $3400 were shipped to Salt Lake City on the 8th inst. The ore milled came from the 250-foot level, which is 100 feet deeper than former workings. This is the 99th shipment of bullion and auro-cyanides from this property under the present management. The property is owned principally in Salt Lake City and is managed by S. B. Milner.

Tuscarora, Sept. 9th, '99.

HUMBOLDT COUNTY.

Winnemucca *Silver State*: J. Taylor of Bloody canyon is arranging to ship sixteen tons of high-grade antimony to San Francisco. The ore is from Mr. Taylor's mine, fifteen miles from Mill City. The ore is high grade.

OREGON.

BAKER COUNTY.

(Special Correspondence). — The Imperial lead of the Eagle group at Cable Cove has a tunnel that taps the vein 200 feet below the surface, from which 225 feet of drifting has been done on the vein. The ores here run as high as five ounces gold, thirty ounces silver and 16% lead. The width of ore of that value runs from 1 foot to 40 inches. This is the property of J. C. Young and associates.

The rich strikes recently made in the Golconda uncovered blocks of sulphurets, tellurium and coarse gold whose values ran up into the thousands. The singular feature of the discovery was that gold in the above-named forms was found after going through a capping of base arsenides and antimonial ores of very moderate grade.

The Golconda mill, involving the apparatus and equipment for treating those ores by the bromo-chlorine-electrical process, has finally been adjudged unsatisfactory by J. G. English, owner of the property, and steps are being taken to discard that process and make such changes in the mill as will adapt it to amalgamation and concentration work.

The Climax vein, adjoining the Golconda, belonging to J. W. Bolland and F. G. Jewett of Baker City, is being developed by them.

F. S. Baillee, who resigned the management of the Columbia, has become manager of the Golconda, T. L. Lammers succeeding him at the Columbia.

The Cayuse group was sold a few days ago by W. Snarr to E. Finch and W. C. Calder. The property is in the Greenhorn range, twenty-five miles from Sumpter.

Sumpter, Or., Sept. 5th, '99. WASCOTT.

The Ibex mine, near Sumpter, was sold last week to the Consolidated Mines Association, of London. The Ibex is on the same ledge as the Baisley-Elkhorn, North Pole, Columbia and Golconda.

Baker City *Epigram*: W. Potter, who put up the Red Boy 20-stamp mill, will build on the Little Giant mine a 20-stamp mill and on the Magnolia and May Queen one of ten stamps each, and a cyanide plant at the Red Boy.

SOUTH DAKOTA.

(Special Correspondence). — Within two years the Two Bit country has had a boom. There are six hoists on as many groups of claims. The Chicago & Two Bit shaft is down 512 feet, and there found the lower quartzite. There are 150 feet of drifts, but no ore body in sight.

A mile above this the Deadwood & Detroit Co. are down 200 feet, in quartzite, with several hundred feet of drifts, and some small shoots of ore. The others are of less importance.

The Hardin Standard mine is down 300 feet in a body of auriferous iron pyrite (low grade).

On Spruce gulch is a body of iron pyrite which was formerly shipped to the D. & D. smelter, but the appearance of blende and galena in the ore rendered it unfit for the pyritic smelter. This deposit is separated from a sheet of porphyry 100 feet thick by a thin sheet of shale. Under the porphyry is shale, which extends to the lower quartzite. The latter has not been explored, though showing galena and pyrite, hematite, manganese, gold and silver. One hundred and fifty feet higher than the bed of pyrite and blende referred to is a bed of shale containing the richest ores in the district, and 100 feet still higher is a horizon containing gold ores. Lying loose upon the surface in some places is quartzite honeycombed with the borings of of fossil insects (arencolites). All of this rock is gold-bearing, but ordinarily low grade. This rock in the Terry peak region is rich in gold and silver ores.

In Ruby basin, east of Terry peak, 500 tons of ore are milled daily. The great silicious telluride ore deposits extend southeasterly and southwesterly from Bald mountain. The ores in this district occur in two systems of shoots, divided by a valley or depression in the quartzite. Upon each side of this depression, and parallel with it, are two large shoots, the larger one being on the west side. Numerous small shoots branch off from these large ones and run often 100 feet, when the ore ceases. There was some ore in the valley described, at the north end of Nevada gulch, near Bald mountain, but as work proceeded southward the ore left the valley and the depression became more sharply defined, and 1800 feet south of Bald mountain no ore is found in the depression for more than 2000 feet.

Deadwood, Sept. 8th, '99.

TEXAS.

ARCHER COUNTY.

Denver *Republican*: A company is attempting to work a copper deposit in this county, of which J. Philbrick says: "We are mining for copper, but instead of finding it in rock we find it in a formation which resembles clay. No one would ever have thought of starting a mine in the place if it had not been for the color of the deposit. A bit of the material was taken to an assayer, and his returns showed high copper values. We haven't done much development work for the reason that we do not know how to go about it. Soft rock is bad enough to mine in, but clay is almost impossible. I have been in consultation with several mining engineers, all of whom have given it up. If we hit upon a reasonably economical method of retaining the walls of our drifts and tunnels we will have a paying thing. The formation is, as far as we can explain it, a large fissure filled with finely ground rock containing mineral matter. The hanging wall and foot wall have not been found. Small uncrushed chips of porphyry are found."

UTAH.

IRON COUNTY.

G. H. Smith says the new strike in the Johnny at Stateline promises to develop into a productive proposition. F. Wilson, who recently sold the April Fool for $100,000, purchased an interest and bid $10,000 for another fifth in the property. The first and second class ores show free gold, and the milling ores average $40 per ton. Of the first class three tons are ready for shipment. The sampling in the bottom of the shaft gave an average of $600 a ton in gold. The mill is to be started up.

L. Bast is working the Vandalia, an extension of the Johnny, and the Ophir is working with a full force.

JUAB COUNTY.

(Special Correspondence).—The Picnic mine at Silver City recently shipped ore from the 650-foot workings. They are drifting with the expectation of getting the South Swansea vein. The ore bodies of the Four Aces, Park and South Swansea come to a junction on the Picnic grounds, it is claimed.

A gasoline hoist has been set at work on the Carressa, near Silver City, and a shaft is being sunk. This property was sold last winter to Smith & Moffatt of Denver, Colo, and is in charge of Supt. Underwood.

Silver City, Sept. 11th, '99.

The Grand Central M. Co., at Tintic, has

commenced action against the Mammoth Co., enjoining the latter from extracting ore from the plaintiff's ground.

Another strike has been made at the Shoebridge Bonanza, Tintic. Manager Heffron reports the vein has been broken into by the drift off the 200-foot level, the entire face showing chloride of silver.

Tintic *Miner*: There is enough shipping ore in sight in the Centennial-Eureka to more than pay the purchase price of the mine, besides several thousand tons of a milling grade.

SALT LAKE COUNTY.

(Special Correspondence).—The Red Wing at Bingham has developed two fine ore bodies, one of which is copper and the other silver and lead. Development consists of a 700-foot tunnel and 300 feet of drifting on the veins. The veins average 60 feet wide. The lead-silver ores are concentrated at the Red Wing mill in the ratio of four and one-half tons into one ton.

Under direction of Capt. DeLamar, thorough exploration has been going on at his holdings near Bingham. Thorough tests have been made with drills and ores from a number of tunnels have been tested. These tests have just been concluded and it is claimed the results are not disappointing.

Work on the Cook group progresses. In driving through the country rock, which is porphyry and quartzite, it is found this material is mineralized, containing fair values.

Bingham, Sept. 11th, '99.

SUMMIT COUNTY.

Park *Record*: Work on the Lucky Bill is to be resumed.——The machinery of the old Anchor concentrator is being moved to the new mill.——Fifteen men are grading for the sinking of the 500-foot shaft on the Putnam ground. The machinery formerly at the Woodside mine will be moved and used on this property.——O. E. Lawrence has secured a lease and bond on the Jupiter mine on Pioneer ridge, and will commence operations.——Foreman Charles Buehler of the Steamboat group reports that property looking well and development progressing. Work will be continued until winter and then abandoned until spring, when machinery will be put in and work resumed.——James Kennelley has a lease and bond on the Silver Key, situated south of the Crescent mine and near the Apex. Men will be put to work next week.

TOOELE COUNTY.

(Special Correspondence).—The Overland at Sunshine is treating about 100 tons per day at its cyanide plant. Development on this mine has progressed well, the vein being opened for 1000 feet on the strike of the vein and to 600 feet in depth on the dip.

The Chloride Point cyanide mill is handling about thirty-five tons of ore per day, the grade running from 15 to 20 ounces silver. The mine is worked through tunnels.

Sunshine, Sept. 10th, '99.

Salt Lake *Tribune*: Capt. De Lamar is examining into Deep creek. R. C. Gemmel, has charge of the expedition. He says he found very little work going on at the camps. The Queen of Sheba has been shut down some time, also the Midas. The greatest activity observed was on Dutch mountain, where M. Evans and associates are operating.

WASHINGTON COUNTY.

(Special Correspondence).—The Dixie M. & S. Co. are operating a copper mine and smelter twelve miles from St. George and fifty-five miles from the Oregon Short Line Railroad at Modina. The vein from which ore is being taken is from 25 to 30 feet wide and is opened through a 426 foot tunnel. The general average of the ore is 16% copper, though select lots have run about 43%. The smelter has two furnaces and handles twenty tons per day. There are also small values in gold.

St. George, Sept. 9th, '99.

WASHINGTON.

KING COUNTY.

Work has been started on what promises to be one of the largest smelting plants in the Northwest at Kirkland. It is expected to be ready for work by January 1st.

STEVENS COUNTY.

The Chesaw district now has 500 inhabitants. The hills are low and rounded and the valleys are fertile and tilled. The C. P. railway will be built within six miles of Chesaw. The character of the ores is like that of Camp McKinney.

Spokesman-Review: The Jim Hill claim at Chesaw is a paying mine. A month ago the Chesaw Imp. Co. commenced work on the old shaft which had been sunk 23 feet, at that depth showing talc and lime-like quartz, carrying small values. At a depth of 50 feet the whole bottom of the shaft was composed of a blue-gray quartz assaying $30 in gold. The shaft is in the middle of the ledge, no walls being in sight.

WYOMING.

Grand Encampment *Herald*: The Rudefeha has struck ore in a crosscut from the working shaft, 150 feet from the original discovery, and 100 feet below the bottom of the old 80-foot shaft. The ore is of the same quality as in the old workings.——A large body of high-grade ore is blocked out.

CARBON COUNTY.

The Supt. of the Wyoming Con. Copper Co.'s mines reports a tunnel 160 feet driven alongside the ledge and a crosscut that shows the richest body of ore to be 12 feet wide, with 50 feet in width more or less mineralized. The shaft being sunk onto the ledge 700 feet from the mouth of the tunnel shows copper glance and chalcopyrite. The tunnel will cut under this point 250 feet. Plans are formed to utilize Big creek to generate electrical power. The developments show that the ledge extends northwest 4500 feet, and southeast there are three miles of claims.

FOREIGN.

AUSTRALIA.

Melbourne *Standard*: Prospectors have found a large reef at Mount Shorter giving good prospects. Other parties are excavating about the surface, but have found ore carrying good but very fine gold, not visible, except in very rare instances, to the naked eye. All the available ground around Mount Shorter is held under lease extending for several miles. In Moppitt's, Mount Shorter, is exposed solid quartz 14 feet wide, which is stated to crush 25 dwt. per ton.——The Great Boulder Perseverance Co., in West Australia, is shipping 800 tons of sulphide ore monthly to the Eastern colonies to be smelted, the assay value of which is six ounces. A start has been made by this company to erect their own sulphide plant, which will be completed in six months.——W. B. Greenwood, a Government prospector, has telegraphed from Worturpa to the Commissioner of Crown Lands the report that a rich vein of gold and telluride had been struck in Bevern's claims, 2½ miles west of the Reward claim, on a parallel ridge of ore.

BRITISH COLUMBIA.

(Special Correspondence.)—In the Virginia workings, at Rossland, a rich shoot of ore was recently opened in a surface cut, on which they are now sinking. The main shaft is down 500 feet, from which a drift runs to the vein. At the 300 level a drift is being run to find the vein that was uncovered at the surface.

Rossland, Sept. 9, '99.

J. Edwards-Leckie, on behalf of Montreal parties, has bonded from E. Spraggett, Grand Forks, and J. M. McGregor, Nelson, Wash., the Yankee Boy and the Bell for $25,000. The properties are on Hardy mountain, three miles from Grand Forks.

Moyie Leader: The Lake Shore at Moyie will begin ore shipments soon.——The Canadian Gold Fields syndicate will erect a concentrator this fall. There are fifty-two men on the syndicate's payroll.——Railway construction in Boundary Creek has resulted in opening several large ledges. Along the North Fork on the Oro Dinero and the Emma the railway grade made important exposures. The latest strike is on the Sunset mine, in Deadwood camp. The branch line from Greenwood to Deadwood and Copper camps opened a lode of rich copper ore.

CANADA.

Five furnace retorts started last week at the mines of the Great Lakes Copper Co. at Sudbury, Ont., and five more are in process of completion.

Large beds of marl and gypsum are being developed near Port Clinton, Ontario.

MEXICO.

It is stated that the richest copper mines in the Republic are in the State of Michoacan. In parts of that State are deposits of copper pyrites, which lie between a flow of andesite and granite.

The so-called copper mines in Lower California, near Cape St. Roque, have been investigated by San Francisco men and are pronounced worthless. The copper occurs as carbonate but in small amount.

SOUTH AFRICA.

Director of the Mint Roberts, in speaking of the effect of hostilities in the Transvaal upon the gold production, says: "Exactly how much the gold production would be curtailed would depend on the duration and extent of the conflict. The little Dutch republic is now the greatest gold producing country in the world. It assumed the lead of all other countries last year, and this year has been making gains over its former record. The total output of the Dutch republic last year was $88,000,000, and that was a great jump from the year before. During the month of July this year its gold output was more than $8,000,000, the largest amount ever taken out in one month. At this rate the yearly output would be nearly $100,000,000, and, including the gold mined in other parts of South Africa, would be fully $100,000,000." The English have the largest interest in the mines; the French and Germans are largely involved. The threat of President Kruger to destroy the mining properties refers to the millions of foreign money invested in machinery for taking out the gold.

Recently Declared Mining Dividends.

New York Zinc Co., dividend 1%; payable Oct. 1st.

Jack Pot, Cripple Creek, Colo., $50,000; payable Sept. 25th.

April Fool mine, De Lamar, Nevada, $5,000; Sept. 15th.

Calumet & Hecla, Michigan, $20 per share; payable Sept. 29th.

Portland M. Co., Cripple Creek, Colo., $60,000; Sept. 15th.

Stratton's Independence, Victor, Colo., $488,000; payable Sept. 25th.

Gwin Mine Development Co., Cal., $5,000; Sept. 12th. Total to date, $86,500.

Elkton Con. M. & M. Co., Cripple Creek, dividend of $30,000; payable Sept. 20th.

Wolverine Copper M. Co., Michigan, semi-annual dividend of $2 per share; payable Oct. 2nd.

An extra dividend of $1 per share has been declared by the Montana Ore Purchasing Co.; payable Sept. 27th.

Yellow Aster M. Co., Cal., monthly dividend, $10,000; Sept. 11th.

Books Received.

"*Slide Valves*," 81 pages octavo, one of a series of practical handbooks, treating of that necessary and important part of the steam engine—the valve—with particular reference to the "slide" variety. Published by Spon & Chamberlain, New York City; $1.

Industrial Notes.

—There are 11,583 soldiers at San Francisco.

—California and South Carolina are producing tea.

—The $5000 water bonds of Seattle, Wash., are ready for delivery.

—The formation of trusts has ceased to be an overcrowded industry.

—Martinez, Cal., contemplates a copper smelter and smokeless powder plant.

—San Luis Obispo, Cal., this week voted $116,000 for improvement of its water system.

—On the 13th inst. messages were sent from England to France by wireless telegraphy.

—The Iowa geological report shows that during 1898 the State of Iowa produced minerals to the value of $7,426,723.

—The sum of $3000 was paid the Brooklyn, N. Y. long distance telephone office for a recent fifty hour talk with St. Louis, Mo.

—The ridiculous project of a canal between Puget Sound and Gray's Harbor, Wash. is advocated by men who ought to know better.

—The Washburn-Moen end of the American Steel & Wire Co. are said to have earned $1,800,000 net for the year ending July 31, '99.

—Denver newspapers call on Coloradoans to patronize home productions wherever practicable, and cease spending money for foreign products.

—Ship carpenters are in demand at San Francisco; $4 for eight hours is paid, with $1 per hour for overtime; those working sixteen hours are paid $12 per day.

—Tin plate is advancing in price, owing to higher price of iron and steel and also to an increase in wages. The raise amounts to about 35 cents per box more than a year ago.

—The electrical plant at the Sperry, Stockton, Cal., flour mill was illustrated and technically described in the issue of August 19th. The electric power for which the Sperry Co. is to pay the Standard Electric Co. is being gauged by the number of barrels of flour turned out by the mill per month.

—The Manufacturers' and Wholesalers' League of San Francisco is securing the presence of purchasers from Texas, New Mexico and Arizona. Similar inducements have also been afforded merchants from Montana, Idaho, Utah and Washington by excursion rates, etc., the intent being to retain the trade.

—The manufacture of steel has been commenced at Minneapolis, where the plant of the Republic Iron & Steel Co. is making open hearth steel only. Under orders from headquarters the mill has ceased to make bar iron, the whole capacity of the mill being devoted to bar steel. The manufacture of bar iron is being gradually discontinued.

—Coal is reported discovered sixty-one miles below Dawson, a mile and three-quarters back from the Yukon river. The N. A. T. & T. Co. has built a railroad from the river to the mine. The coal is still frozen at a depth of 250 feet below the surface. Recently 1250 tons were shipped to Dawson. The Canadian Government took 250 tons at $30 per ton.

—Sacramento, Cal., is using electric power transmitted 65 miles over aluminum wires from Brown's valley, the first installment of 1000 H. P. sent by the North Yuba Co. under contract with the Sacramento Electric, Gas & Ry. Co. of Sacramento, and supplements power already used and transmitted here from Newcastle and Folsom. Under contract 4000 more H. P. is to follow.

—The town of Mountain View, Oklahoma, was recently organized. A rival town existed about a mile and a half west, and it was deemed advisable to consolidate it with Mountain View. The rival, Oakdale, was purchased entire for $34,380, and is now being transported to Mountain View. On the same principle the citizens of Skaguay, Alaska, are about to undertake a big enterprise. Dyea is to be taken up—the whole town at the entrance to the Chilkoot pass—and moved across Lynn canal on scows to Skaguay to augment the growing town at the head of Lynn canal. E. Foreman of California has secured 320 buildings, large and small, according to a local report.

—By an expenditure of nearly $600,000 the power of the Santa Ana river is transmitted to Los Angeles, Cal., eighty-two miles distant, and 9000 H. P. propels machinery, moves street cars and illuminates buildings in Los Angeles, Redlands, Riverside, Colton and Ontario. The most remarkable feature in this development of electrical power is the transmission of electricity of a high voltage over eighty miles of wire with so little loss of energy, the company finding, in fact, that it can send electricity of 33,000 volts, having a working efficiency of 4000 H. P., a distance of eighty-three miles, with a loss of but 10%. After doing its work in the production of electrical energy, the mountain stream is gathered into a conduit and led down the mountain side to irrigate the orchards and groves in San Bernardino valley.

Commercial Paragraphs.

THE Vulcan Iron Works of San Francisco is putting in the third ice plant supplied by this firm to Manila merchants.

THE Redlands Railway Co. have nearly completed their new electric system. All of their light rail was sold to Lee Chamberlain & Co., Los Angeles, Cal.

Obituary.

GEORGE HAINES WOODBURY, of San Francisco, died at Sydney, Australia, on the 6th inst. Deceased was the son of Geo. E. Woodbury, and had recently gone to Australia on business for his father. He was a graduate of the Massachusetts Institute of Technology and was just entering on a useful manhood.

Personal.

AUG. J. BOWIE has returned to San Francisco from Dawson.

T. A. RICKARD of Denver, Colo., has gone to southern Arizona to examine mines.

PATRICK CLARK of the Cœur d'Alenes has made Spokane, Wash., his permanent home.

WM. MCSORLEY has been appointed shift boss at the Daly-West mine, Park City, Utah.

F. H. CHERRY, traveling representative Vulcan Iron Works, San Francisco, is in Manila.

EBEN SMITH AND R. H. REID of Leadville, Colo., are in Utah looking after their interests there.

JOS. MCGILLIVRAY, the veteran California miner, has returned to Dawson, N. W. T., from London, Eng.

CLARENCE S. KING, formerly of Los Angeles, Cal., has purchased the assay business of Wallace & Hart at Baker City, Or.

A. L. DICKERMAN of Colorado Springs, Colo., has recently visited Jerome, Ariz., in the interest of John D. Rockefeller & Co.

AUGUST RHAUTT, formerly with the Philadelphia Smelter at Pueblo, Colo., is now Supt. Arkansas Valley Smelter, Leadville, Colo.

CAPT. W. M. JAMES and son of Shasta Co., Cal., will return to Johannesburg, South Africa, next month, if the present war cloud blows over.

A. D. MOFFITT, formerly foreman of the Ontario mill, at Park City, Utah, has been engaged to superintend the Bimetallic mill, near Phillipsburg, Mont.

F. WING of the Seattle, Wash., United States Assay Office, expects $2,000,000 additional gold dust from the North before the output ceases for the season.

MRS. NELLIE YEAGER, Dawson City, N. W. T., sends word that if her papa will send her his picture she will send him a check for $1000. He is Capt. Matthew Chance.

L. M. DAVIS AND R. B. ARCHIBALD of London, Eng., and Supt. Gallagher of the Anaconda mine are investigating the copper prospects of western Washington.

W. P. HANCOCK is at Cuprum, Idaho. He brought several California miners with him, and is superintending the operations of the Boston & Seven Devils Copper Co.

CAPT. M. A. HEALEY of the United States revenue service has returned to San Francisco from an extended inspection of the mining camps along the Alaskan coast.

THOS. A. EDISON denies the statement that he had bought the Ortiz, N. M., land grant, but says he is building one of his magnetic ore-extracting machines for use thereon.

GOV. A. R. SHEPHERD denies the recent statement wired to the New York press that he had sold his mining property at Batopolas, Mexico, and would return to Washington, D. C.

JOHN T. ENGLISH, of Baker City, Or., is in San Francisco buying machinery for his mine. It is understood that the result of the bromo-chlorination process at his mill is not an unqualified success.

W. R. ECKART AND W. F. PIERCE have charge of the buying of supplies for the Standard Electric Co., which proposes to issue $5,000,000 in its scheme of San Francisco electric transmission.

W. A. CARLYSLE, formerly mineralogist of the Province of British Columbia, now Supt. Le Roi mine at Rossland, is locally reported to have been offered the position of Mgr. Rio Pinto mines, in Spain, at an annual salary of $25,000.

I. TRUMBO has been appointed receiver of the Golden Cross mine, Hedges, Cal., thus practically ending the litigation over the property. The claim of retiring Receiver Pauly for $1000 per month salary and $2500 attney's fees was allowed.

J. R. DELAMAR AND HARTWIG COHEN left San Francisco on the 12th inst. for Paris via New York City. Capt. DeLamar says he will put 100 men at work at his newly acquired Bully Hill, Cal., property, and has no plan for smelters until he learns what kind of treatment is required.

R. A. PARKER has returned to San Francisco from Utah. While there, in company with A. F. Holden and J. W. Neill, he made an examination of the Centennial-Eureka, which, upon recommendation has been bought by the U. S. Mining Co. of Boston, Mass.; capital stock, $5,000,000.

J. M. CARMICHAEL, H. H. Keyes, W. S. Steel, Arch. Milligan, H. P. Anderson, H. B. Boyer, A. J. Pesnell, Jos. Kampachner, B. Evans and H. Harlan, form a party of Prescott, Arizona, miners who have gone to Peru, S. A., under a contract with C. P. Collins, to explore the mining region on the east slope of the Andes.

C. F. HOFFMANN, who for several years was Supt. Red Point mine, near Damascus, Placer Co., Cal., and who left about three years ago for Siberia, has returned to San Francisco. Mr. Hoffmann says there are good mines in Siberia, but that the existing conditions render their operation a hardship. Owing to the difficulty of obtaining supplies and improved American machinery, the development is slow, and, added to this, the tax imposed by the Government, amounting to about 17% of the output, is almost prohibitive and would in itself constitute a good dividend. More recently Mr. Hoffmann has been in Argentine Republic, South America. He says there are good mines there, but the best ones are found at an altitude of about 15,000 feet above the sea, where there is neither timber nor water and little air.

List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey, Strong & Co., Pioneer Patent Solicitors for Pacific Coast.

FOR THE WEEK ENDING SEPT. 5, 1899.

632,592.—BINDER AND LEDGER—Sol Adler, S. F.

NOTE.—Plain and Certified Copies of U. S. and Foreign patents obtained by Dewey, Strong & Co., by mail or telegraphic order. American and Foreign patents secured, and general patent business transacted with perfect security, at reasonable rates, and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey, Strong & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

SLIDABLE AND SWINGING WINDOW SASH.—Bernard Hausmann, San Francisco, Cal. No. 632,411. Dated Sept. 5, 1899. This invention relates to a mechanism for sliding window sashes and a means for disengaging such sashes so that they are turnable about hinges to swing inwardly for the purpose of obtaining access to the outside of the sash. It consists of guided, grooved and shaped slides to one of which one edge of the sash is hinged; a hook or hooks upon the opposite edge of the sash, and corresponding loops upon the slide with which the hooks engage when the sash is closed, a means for retaining in place and preventing the slide from moving upwardly when the sash has been disengaged therefrom, which consists of a stop or channel upon the slide and a yoke horizontally slidable, so as to engage with this stop or channel or be disengaged therefrom.

COLD STORAGE APPARATUS.—J. T. Ludlow, San Francisco, Cal. No. 632,356. Dated Sept. 5, 1899. This invention comprises a cold storage room in which meat may be either hung up or packed in bulk, and a convenient method for changing from one system to the other, and to secure a natural and even circulation of cold air around the outside of the bulk of packed meat. The rooms have non-conducting walls with stanchions and cross-bars removably fixed near said walls to form spaces, and other stanchions intermediate between the ends of the rooms, forming an open space larger than those contiguous to the walls, and through which access may be had. Stringers with transverse bars are fixed upon the floors so that the ends and central spaces are connected, and refrigerating pipes are disposed along the ceiling and around the upper part of the packing spaces. Below the lines of pipes are parallel bars having hanging hooks fixed to them, and hanging bars, the upper ends of which are fixed to the deck beams and are so formed as to support the refrigerating pipes and the hook-carrying bars.

LOOSE LEAF BINDER AND LEDGER.—Sol Adler, San Francisco, Cal. No. 632,391. Dated Sept. 5, 1899. This invention is designed as a temporary binder of that class which are designed to contain removable leaves, and which are made to form ledgers and other like books where it may be desired to temporarily bind together and lock the leaves in place, but at the same time provide a means by which the leaves may be removed when desired. It comprises a chambered back having a cover hinged at one side, a guided plate carrying the opposite cover and movable with relation to the back to increase or decrease the distance between the covers. Segmental posts are fixed so that one slides upon the other, and when they are together they form a complete cylindrical post. The sheets which are to be held upon these posts are perforated, and have slots opening out from one side, these slots fitting and being held by a rib which projects from one of the segmental posts, so that when the parts are all put together the leaves are locked in place, but when the part of the post having the rib is slipped upwardly, it allows the leaves to be disengaged or replaced at will.

Hoskins' Patent Hydro-Carbon Blow-Pipe and Assay Furnaces.

No dust. No ashes. Cheap, effective, economical, portable and automatic.

SEND FOR PRICE LIST TO

Hyposulphite of Soda
Chloride of Lime
Sulphide of Iron

And other Chemicals for Mining Purposes.

Can I Become An Electric Mining Engineer?

YES, You Can. We guarantee we can make a thorough electric mining engineer of you at your home by our new system of correspondence instruction. Our instruction papers are prepared by the highest authorities and include every branch and method employed successfully to-day in electric mining. Course includes: General conditions of mines; Systems for the application of power; Mine wiring; Signaling; Electric haulage; Hoisting motors; Operation of electric mining installations; Cost of electric mining equipment, etc. Our terms are within reach of all; $5 or $2 per month or cash in advance. *Write for our free illustrated book* (120 pages); it will pay you to read it. We teach also **Electrical and Mechanical Engineering, Mechanical Drawing,** Telegraphy, Telephony, etc., by mail. THE ELECTRICAL ENGINEER INSTITUTE OF CORRESPONDENCE INSTRUCTION, Dept. 21, 120-122 Liberty Street, New York.

I consider the Electrical Engineer Institute as conducted by Messrs Wetzler and Martin to be of great value to those who desire an Electrical Education

30 in. x 72 in. Direct Acting Hoisting Engine

BUILT FOR THE

Anaconda Copper Mining Company

OF MONTANA.

Embodying all that experience and practical working have demonstrated as valuable in this class of machinery.

The brakes, clutches and reversing gear are arranged to be operated by compressed air or steam, by means of auxiliary cylinders which are under full control of the engineer, stationed upon the elevated platform shown, insuring the most rapid work with absolute safety. Shaft hollow forged steel of ample strength and stiffness to withstand any strains; reciprocating parts of steel and are as light as consistent with the duty required; cylinders of the "overhung" type, weight being taken by a guide saddle, which admits of free longitudinal movement, due to expansion, causing no strain on bed plate or foundations; cylinders steam-jacketed, fitted with valves provided with Corliss releasing gear and hand cut-off, enabling the engines to be run economically with reference to the work to be performed; bed plates modification of the Porter Allen type, heavy and substantial, with large foundation base and anchor bolts. A duplicate of this engine has also been furnished the Homestake Mining Company of Dakota.

WHITE, ROGERS & CO.,

Contracting Engineers and Millwrights,

OFFICES, 306 PINE STREET, - - SAN FRANCISCO, CAL.

Sole Pacific Coast Agents and Builders of the Celebrated

WILFLEY CONCENTRATOR.

The Wilfley Table is fully covered by U. S. patents Nos. 580,338 and 590,675. Infringements will be prosecuted to the full extent of the law.

PRICE, $450, F. O. B., San Francisco.

One of these machines will take the place of two or three belt concentrators of any style and do very much better work. Easy adjustment. Little wear.

Some Practical Reasons Why the Wilfley Concentrator Should Be Used in Gold Mills:

1. It will successfully handle three or four times more material than any belt Concentrator made, without exception.
2. It will save more sulphurets in proportion while so doing, and catch any float gold, amalgam or quicksilver which may escape from mortars or plates.
3. It will make cleaner and much more valuable concentrates, thus saving useless expense for transporting valueless material, as also extra cost for treatment.
4. It requires little or no attention when once adjusted and no expert is required to either adjust or run the machine.
5. It will save much expense in power and room, and the first cost of a mill requiring concentrators.
6. It has no expensive belts to crack and wear out, nor complicated machinery to keep in repair.
7. It is the only sensible plan of concentration, as any kind of material can be worked, which is not true of any style of belt machine.

SEND FOR CIRCULARS.

These Machines are Kept in Stock Ready for Immediate Shipment.

The above illustration shows the method of holding and sighting BRUNTON'S PAT. POCKET MINE TRANSIT, when taking courses or horizontal angles. The construction is such as to permit of simultaneous sighting and reading. No tripod or Jacob's staff is necessary, and an operator, after becoming accustomed to its uses, can take the Transit from his pocket, take a reading and replace the instrument before a sighting compass can be placed. The most accurate and reliable pocket instrument on the market. Send for illustrated Catalogue B to

No. 1 Special Button Balance with 8-inch beam. Sensibility 1-200 Milligramme. For very accurate weighings. Among the well-known smelters using this balance are the following: GLOBE SMELTING & REFINING CO., Denver, Colo., U. S. A.; CANADIAN SMELTING WORKS, Trail, B. C.; MT. LYELL MINING & RAILWAY CO.'S Reduction Works, Penghana, Tasmania.

P&B ROOFING

ROOFING is to a building what clothing is to the body. It must protect and it must wear well. To put money in an interior and to save it on the roof of a building is poor economy.
P & B ROOFING possesses all the requirements of a first-class roof covering. It is waterproof, durable, inexpensive, easily laid. Ask your dealer for a circular, or address the makers.

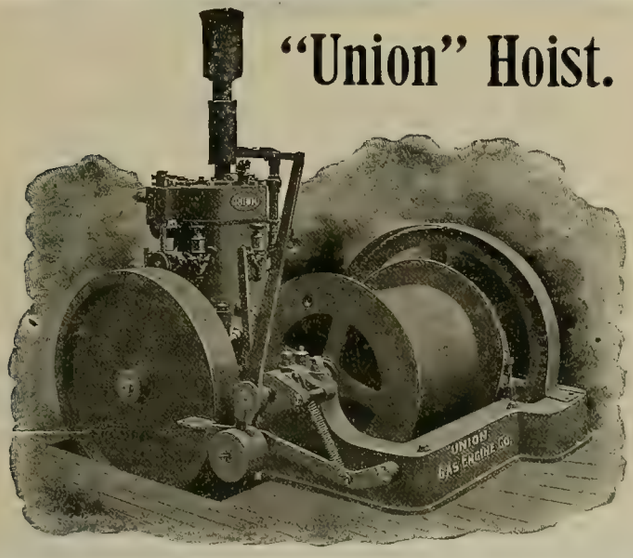
THE BRYAN ROLLER QUARTZ MILL.

We are the sole manufacturers of this Mill. A test made by the Bullion-Beck Co. of Eureka, Utah, with this and the Huntington Mill proved conclusively every claim we made for the Bryan Mill, viz: that the Bryan would crush more ore with less repairs, less power and less slimes than any Mill made. Result—they are now operating three of the five-foot Bryan Mills and find them superior and more satisfactory than any Mill they ever used. L. C. Trent & Co., who had formerly sold the Huntington Mill, immediately manufactured a Mill infringing our patent. Suit brought in the U. S. Court resulted in a verdict in our favor, and we shall prosecute to the full extent of the law any infringement of any character whatsoever in the MAKING, USING or SELLING of the same. : : : : : : : : : : :

Strong.
Economical.
Simple.

MANUFACTURED BY



◆◆◆◆◆◆◆◆◆◆◆◆

The BRYAN MILL is constructed on the principle of the Chili Mill, except it has three rollers arranged to run in a continuous discharging pan. It crushes either gold or silver ores. It consists of an annular cast-iron mortar with fixed steel dies arranged in the path of its three crushing rollers. Power is applied direct from a pulley through a bevel gear and pinion secured to stationary center post. We present a few of many advantages it possesses over any other Mill: Larger screen capacity and free discharge. Amalgamates a larger percentage of gold. Quickly and cheaply erected; with regular feed and proper flow of water requires little attention. Crushes hard or soft ore with smaller amount of power per ton and less wear and tear of machinery. : : : :

Send for Catalogue No. 8.

Sole Manufacturers of

Kendall's Patent Quartz Mills.

Having renewed our contract on more advantageous terms with Mr. S. Kendall for the manufacture of his Patent Quartz Mill, we are enabled to offer these mills at **Greatly Reduced Prices.** Having made and sold these mills for the past 16 years, we know their merits, and know that they have given perfect satisfaction to purchasers, as numbers of commendatory testimonials prove. We feel confident, therefore, that at the prices we are now prepared to offer them, there is placed within the reach of all a light, cheap and durable mill that will do all that is claimed for it and give entire satisfaction.

"The Proof of the Pudding is in the Eating."

Something over a year ago, two of these Richards' Patent Triple Plunger Pumps, with motors as shown, were supplied to a mine in Mexico, for the purpose of raising water to an elevation of 650 feet. The owners were so well pleased, that they ordered another of the same a few months later. These pumps were arranged with outside packed plungers, for pumping muddy water — designed for that purpose, they did it satisfactorily.

For all purposes where a uniform resistance to the driving motor is a consideration, these pumps are admirably adapted. Triple Plungers and crank shafts run in a bath of oil if desired. Made with large valve areas, and by actual test develop a very high efficiency. Furnished with or without motors, or for use with gas or steam engine.

This is only one of over fifty different kinds of pumps we make.
Our 1899 Catalogue tells all about them; sent on application.

THE IDEAL CONVEYOR BELT

LEVIATHAN

Is the one that will carry stone, ore, coal, wet or dry material, holding buckets firmly and securely; will stand all kinds of exposure, and resist the heaviest strains during a long period of service. This is what the **LEVIATHAN BELT** has done, and we quote the following from a letter from the New York Steam Co.:

"We have used Leviathan Belting for four years, up to 24-inch by 8-ply, elevating and conveying coal. Some of the Belting is outside, exposed to freezing weather; some in a steam bath. In both conditions the results have been very gratifying, over 500 tons having been handled in ten hours time."

The most modern, completely equipped and up-to-date plant in the Northwest. Everything new from end to end.

GATES FINE CRUSHER.

The result of ten years' solid work. Success at last. What we wanted, and the public demanded, was a Gates Gyratory Rock and Ore Breaker (always adjustable and indestructible) so modified in design as to make one-half-inch product from three-inch sizes, rapidly and cheaply. The H Fine Crusher will do this work. It takes the place of expensive big rolls and often prepares ore, without further crushing, fine enough for coarse concentration or cyaniding. In any event, it is the greatest and best intermediate machine between the coarse breaker and the pulverizer.

Market Reports.

SAN FRANCISCO, Sept. 14, 1899.

SILVER. — London, 27¼d; New York, 59; San Francisco, 59; Mexican Dollars, 48@49; New York exchange, sight, 12½; telegraphic, 15 cents premium.

Silver shows a slight decline, both in Europe and America. There has been a downward tendency for several months past, though the decline has been very slow.

LEAD. — New York reports unchanged, $4.60 bid, $4.62½ asked; brokers' price, $4.40. Local, pipe, 7¼@7½c; sheet, 7¼@8¼c; pig, 6¾c; bar, 6¾c.

COPPER.—New York reports Lake very quiet at $18.50; brokers' price, $18.50. Local —Mill copper plates, 23¾c.

There is a firm appearance to the copper market, with 18¼ bottom notch, while in certain quarters 18¾ has been quoted. The trading is moderate and consumers are not purchasing at current rates. Danger of foreign complications has had no perceptible effect on the market here as yet. London advices report the trading there as insufficient to move prices.

IRON.—American, soft, $22.50@24.50 per ton; Scotch, $27.50 Local bar, 2¾c per lb.

STEEL.—11¼@20c per pound.

TIN.—Steady, with sellers' at $32.80; pig, 36@39c per lb.

ANTIMONY.—In San Francisco 1000 pounds and upwards, 10c net; 300 to 500 pounds, 11@14c; less than 100 pounds, 15c.

BABBITT METAL.—No. 3, 8¾c.

QUICKSILVER.—Unchanged. Local, $45.50; export, $40.50@41; carload lots, special rates.

There is no change to note in quicksilver this week. The demand remains firm and production, being largely under control, is uniform. The newly inaugurated enterprises have as yet made no showing in the market. Mines cannot be opened, furnaces constructed and production commenced without necessary preparation.

PLATINUM. — London, 63½s per ounce; York, $16.25; San Francisco, $16.75.

ALUMINUM.—No. 1, 99% pure in ingots, for remelting, 37c per pound, in small lots; 35c per pound in 100-pound lots; 33c per pound in ton lots and over. No. 2 grade, 90% pure, cast in ingots for remelting, 34c per pound in small lots; 33c per pound in 100-pound lots; 31c per pound in ton lots and over. Aluminum castings, according to number, weight, moldings, etc., 45c per pound, upward. Aluminum sheet from 38c per pound upward. Lots of less than 50 pounds, 5c per pound higher. Nickel aluminum casting metal, 39c per pound in small quantities; 35c in 100-pound lots and 33c in ton lots.

ASSAY LITHARGE.—100 lbs., 12c.

POWDER.—F. o. b. San Francisco: No. 1, 70% nitro-glycerine, per lb., in carload lots, 15½c; less than one ton, 17½c. No. 1*, 60%, carload lots, 13¾c; less than one ton, 15½c, No. 1** 50%, carload lots, 11¾c; less than one ton, 13¾c. No. 2, 40%, carload lots, 10c; less than one ton, 12c. No. 2* 35%, carload lots, 9¾c; less than one ton, 11¼c. No. 2** 30%, carload lots, 9c; less than one ton, 11c. Black blasting powder in carload lots, minimum car 728 kegs, $1.50 per keg; less car lots, $2 per keg.

FUSE.—Triple tape, $5.10 per 1000 feet; double tape, $4.35; single tape, $3.45; Hemp, $3; Cement No. 2, $4.35; Cement No. 1, $3.45.

CAPS.—3x, $5.50 per 1000; 4x, $6.50; 5x, $8; Lion, $9.

CHEMICALS.—Cyanide of potassium, 98%–99%, jobbing, 32@33c ℔ lb.; carloads, 29@30c; in 10-lb. tins 37c; sulphuric acid, 1¾c per lb. 66% B.; soda ash, $1.60 per 100 lbs. 58%; hyposulphite of soda, 2½@2¾c per lb.; blue vitriol, 5¾@6c per lb.; borax, concentrated, 7@8c per lb.; chlorate of potash, 12@13c; roll sulphur, 6c; alum, $1.90@2.00; flour sulphur, French, 2½@2¾c; California refined, 1⅞@1¾c; nitric acid, in carboys 8c per lb; caustic soda, in drums, 3@4c per lb.; Cal. s. soda, bbls., 65c; sks., 60c ℔ 100 lbs; chloride of lime, spot, 2.10@2.25c; nitrate of potash, in kegs, 8c; chlorate of potash, 25c; caustic potash, 10c in 40-lb. tins.

CANDLES.—Electric Light Candles—6s, 16 oz., 8¾c; 6s, 14 oz., 7¼c; 6s, 12 oz., 5¾c; 6s, 10 oz., 5¼c; Granite (Mining) Candles—6s, 16 oz., 9¼c, 6s, 14 oz., 8¼c; 6s, 12 oz., 7¼c; 6s, 10 oz., 6¼c. Paraffine Wax Candles—1s, 2s, 4s, 6s, white, 10c; colored, 11c.

OILS.—California Castor, pure, cs., $1.10 per gal.; bbl., $1.05; pure No. 2, cs., 85c; bbl., 80c; Baker's AA Castor Oil, in case lots of 200 gals. and upward, $1.15; less than 200 gals., $1.10; in bbls., 4c per gal. less than case; Baker's Crystal, $1.40; China Nut, 50c; Linseed, strictly pure, boiled, bbl., 50c; cs., 55c; raw, bbl., 48c; cs., 53c; lots of 5 bbls., 1c less; Lucol, boiled, bbl., 44c; cs., 49c; raw, bbl., 42c; cs., 52c; lots of 5 bbls., 1c less. Kerosene—Pearl, cs., per gal., 16¼c; Astral, 16½c; Star, 16½c; Eocene, 18½c; Extra Star, 20½c; Elaine, 21½c; Water White, bulk, in tanks, 11½c; Mineral Seal, iron bbls., 21c; wooden bbls., 23½c; cs., 26c; Mineral Sperm, 27c; Deodorized Stove Gasoline, bulk, 16c; do., cs., 21c; 86 deg. Gasoline, bulk, 21c; do., cs., 26c; 63 deg. Naphtha or Benzine, deodorized, in bulk, per gal., 15½c; do., in cs., 20½c; Lard Oil, Extra Winter Strained, bbl., 47c; cs., 52c; No. 1 bbl., 42½c; cs., 47½c; Neatsfoot Oil, bbl., 55c; cs., 65c; No. 1 bbl., 47c; cs., 52½c; Sperm, crude, 60c; Natural White, 65c; Bleached do., 70c; Whale Oil, Natural White, 40c; Bleached do., 45c; Cocoa, cs., 55c; Pacific Rubber Mixed Paints, white and house colors, $1.25@1.35 per gal.; wagon colors, $2@2.25.

MINE PROMOTERS, AND BROKERS.
Make a specialty of promoting, operating and developing mines. We handle all standard stocks.
Our specialties are: Syndicate G. M. Co., Syndicate Camp, Idaho; Admiral Dewey G. M. Co., Republic, Wash.; Mabel G. M. Co., Republic, Wash.; Juno M. & M. Co., Republic, Wash.; Ninety-Eight G. M. Co., Republic, Wash. Send for free maps of Republic Camp. Codes used: Moring & Neal and Clough's.

FROM $3 TO $5
WHILE YOU WERE WAITING.

July 20 our stock was placed upon the market at $3 per share. It has advanced steadily since then until it is selling now at $5. Par value of each share is $ 0. which it will sell for by January. There are but 1000 shares offered at $5 per share. If you want to double your money in four months, with the possibility of making 1000 per cent when oil is struck, now is the opportunity.

PATENTS
DEWEY, STRONG & CO'S PATENT AGENCY.
Our U. S. and Foreign Patent Agency presents many and important advantages as a Home Agency over all others, by reason of long establishment, great experience, thorough system, intimate acquaintance with the subjects of inventions in our own community, and our most extensive law and reference library, containing official American reports, with full copies of U. S. Patents since 1872. All worthy inventions patented through DEWEY, STRONG & CO.'s Patent Agency will have the benefit of a description in the *Mining and Scientific Press*. We transact every branch of patent business, and obtain patents in all countries which grant protection to inventors. The large majority of U. S. and foreign patents issued to inventors on the Pacific Coast have been obtained through our agency. We can give the best and *most reliable* advice as to the patentability of new inventions. Our prices are as low as any first-class agencies in the Eastern States, while our advantages for Pacific Coast inventors are far superior. Advice and circulars free.

Assessment Notices.

KATE HAYES MINING COMPANY.—Location of principal place of business, San Francisco, California; location of works North San Juan, Nevada County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 24th day of August, 1899, an assessment (No. 7) of One Dollar per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the secretary, at the office of the company, 320 Sansome street, room 24, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 26th day of September, 1899, will be delinquent and advertised for sale at public auction; and, unless payment is made before, will be sold on WEDNESDAY, the 18th day of October, 1899, to pay the delinquent assessment, together with the costs of advertising and expenses of sale.

By order of the Board of Directors.

JOSEPH H. MOOSER, Secretary

Office—320 Sansome street, room 24, San Francisco, California.

BADGER HILL AND CHEROKEE GRAVEL MINing Company.—Location of principal place of business, San Francisco, California; location of works, Cherokee, Nevada County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 24th day of August, 1899, an assessment of Three Dollars per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the secretary, at the office of the company, 320 Sansome street, room 24, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 27th day of September, 1899, will be delinquent and advertised for sale at public auction; and, unless payment is made before, will be sold on THURSDAY, the 19th day of October, 1899, to pay the delinquent assessment, together with the costs of advertising and expenses of sale.

By order of the Board of Directors.

JOSEPH H. MOOSER, Secretary.

Office—320 Sansome street, room 24, San Francisco, California.

CONSOLIDATED CALIFORNIA & VIRGINIA Mining Company.—Location of principal place of business, San Francisco, California; location of works, Virginia Mining District, Storey County, Nevada.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 6th day of September, 1899, an assessment (No. 14) of 25 cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the secretary, at the office of the company, room 29, Nevada Block, No. 309 Montgomery street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 11th day of October, 1899, will be delinquent and advertised for sale at public auction; and unless payment is made before, will be sold on WEDNESDAY, the 1st day of November, 1899, to pay the delinquent assessment, together with the costs of advertising and expenses of sale.

By order of the Board of Directors.

A. W. HAVENS, Secretary.

Office—Room 29, Nevada Block, No. 309 Montgomery street, San Francisco, California.

EUREKA CONSOLIDATED DRIFT MINING COMpany.—Location of principal place of business, San Francisco, California; location of works, Forest Hill Divide, Placer County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 10th day of August, 1899, an assessment (No. 20) of one-half cent per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the secretary, at the office of the company, No. 1209 Claus Spreckels building, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 12th day of September, 1899, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on SATURDAY, the 30th day of September, 1899, to pay the delinquent assessment, together with the costs of advertising and expenses of sale.

By order of the Board of Directors.

J. J. CRAWFORD, Secretary.

Office—1209-11 Claus Spreckels building, San Francisco, California.

POSTPONEMENT.

The date of the delinquency of the foregoing assessment (No. 20) has been postponed to TUESDAY, the 19th day of September, 1899, and the day of sale from the 30th day of September, 1899, to SATURDAY, the 7th day of October, 1899.

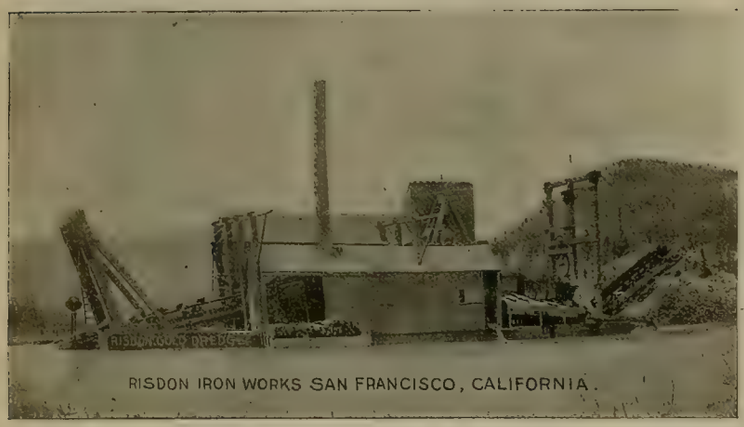
SHEET IRON & STEEL PIPE

FOR TOWN WATER WORKS.

Hydraulic, Irrigation and Power Plants, Well Pipe, Etc., all sizes.



46 FREMONT STREET, SAN FRANCISCO, CAL.

Iron cut, punched and formed, for making pipe on ground where required. All kinds of Tools supplied for making Pipe. Estimates given when required. Are prepared for coating all sizes of Pipes with Asphaltum.

RISDON IRON WORKS,

SAN FRANCISCO, CALIFORNIA.

Cable: "Risdon's." Code: A. B. C. & Leiber's.

MANUFACTURERS OF

Gold Dredging Machinery

And COMPLETE EQUIPMENT for Placer Mines

OUR SPECIALTY.

We build **GOLD DREDGES COMPLETE IN RUNNING ORDER** to handle 2500 cubic yards per day at a cost of 3 cents per cubic yard.

We excavate 50 feet below water, 20 feet above water and handle boulders up to one ton weight.

Send for Dredging Catalogues Nos. 15 and 16.

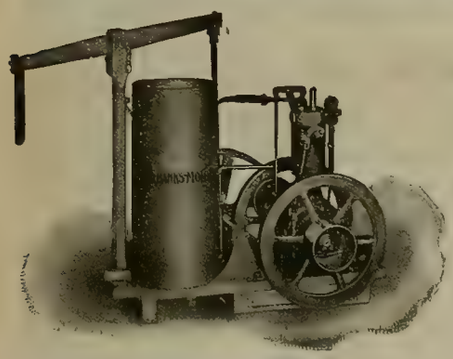
—WE ALSO BUILD—

All kinds of Mining, Milling, Concentrating, Pumping, Air Compressing, Hydraulic, Water Wheel and Hoisting Machinery.

EVANS HYDRAULIC GRAVEL ELEVATORS.

We publish sixteen catalogues. Write for one in the line you are interested in.

THE HALLIDIE ROPEWAY



For transporting Ore, Fuel, Merchandise, etc., in bulk or in packages.
SIMPLE, ECONOMICAL, INEXPENSIVE, PRACTICAL.

LOADS MECHANICALLY. DUMPS AUTOMATICALLY. Send for Ropeway Pamphlet No. 20.

Cableways, Incline Planes,
Double Rope Tramways, Logging Machinery,
Wire Rope Transmissions, Suspension Bridges,

DESIGNED, FURNISHED, ERECTED. Write for Estimates.

CALIFORNIA WIRE WORKS, - 9 Fremont St., San Francisco, Cal.

"JACK OF ALL TRADES" is provided with Walking Beam (with 5, 8 or 10-inch stroke), Belt Pulley, Torch Igniter, Electric Igniter, Battery and Cooling Tank. Can be lifted by four men.

FAIRBANKS-MORSE

"JACK OF ALL TRADES."

A complete Engine of 1½ Horse Power, which will give excellent results with either gasoline or distillate. Powerful, compact and easily handled. Can be useful on every mine.

SEND FOR SPECIAL CATALOGUE.

FAIRBANKS-MORSE GASOLINE ENGINES.
ALL SIZES UP TO AND INCLUDING 54 HORSE POWER.

FAIRBANKS, MORSE & CO.,

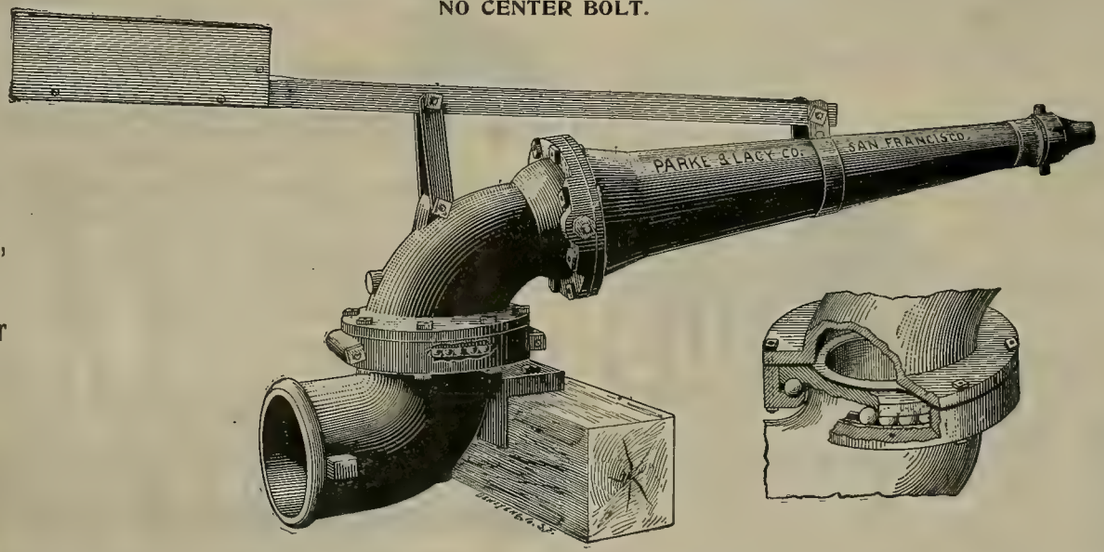
310 Market Street, SAN FRANCISCO, CAL.
201 N. Los Angeles St., LOS ANGELES, CAL.

CORRESPONDENCE SOLICITED.

SIMMONS PATENT DOUBLE-JOINTED, BALL BEARING GIANTS,

With Weighting Attachment.

NO CENTER BOLT.



Deflectors,

Retorts,

Water Gates,

Hydraulic Water PIPE.

Valves, Etc.

Huntington Quartz Mills,

Paul Ball Mill,

Rock Breakers,

Rolls, Etc.

PARKE & LACY CO., 21 and 23 Fremont Street, San Francisco, Cal.

Agent for KNOWLES PUMPS and PULSOMETER PUMPS.

MINING AND SCIENTIFIC PRESS.
AND PACIFIC ELECTRICAL REVIEW.

No. 2046.—VOLUME LXXIX. Number 13. SAN FRANCISCO, SATURDAY, SEPTEMBER 23, 1899. THREE DOLLARS PER ANNUM. Single Copies, Ten Cents.

The American Institute of Mining Engineers.

The largest technical society in America is the American Institute of Mining Engineers. It was organized by Richard P. Rothwell at Wilkesbarre, Pa., in 1871. The first president was David Thomas, who is referred to as the father of the anthracite iron business in America. At present the personnel of the official staff is as follows: President, James Douglas, New York City; vice-presidents—E. D. Peters, Jr., Dorchester, Mass.; Albert R. Ledoux, New York City; Leon P. Feustman, Mexico City; E. C. Potter, Chicago, Ill.; Geo. F. Kunz, New York; W. N. Page, Ansted, W. Va.; managers—C. W. Goodale, Great Falls, Mont.; Frank Lymar, Brooklyn, N. Y.; Frank McM. Stanton, Houghton, Mich.; Richard P. Rothwell, New York; W. J. Olcott, Duluth, Minn.; W. B. Devereux, New York; Arthur Winslow, Kansas City, Mo.; William Glenn, Baltimore, Md.; W. J. Taylor, Bound Brook, N. J.; secretary, R. W. Raymond, New York; treasurer, Theo. D. Rand, Philadelphia, Pa. Portraits of a number of these gentlemen appear on this page, from photographs especially provided therefor. James Douglas, the president of the Institute, is a prominent figure in the mining and metallurgical world, and has contributed numerous valuable technical papers to the Institute, which have been published in its transactions.

JAMES DOUGLAS, New York, President.

Edward D. Peters, Jr., one of the vice-presidents now in office, has become familiar to mining men through his works on copper smelting and his contributions to the literature of the Institute.

Rossiter W. Raymond, Ph. D., one of the earliest vice-presidents of the association and at one time president, has for years been the secretary of the institute, performing the manifold and arduous duties of that office with distinction to himself and to the eminent satisfaction of the members, as attested by his regular re-election at each annual meeting. The name of Dr. Raymond has long been familiar in the mining world through his work as United States Commissioner of Mineral Statistics, and through "Mineral Resources West of the Rocky Mountains, issued by the Interior Department in the early '70s. Dr. Raymond is the author of some of the most val-

THEO. D. RAND, Philadelphia, Treasurer

TABLE OF CONTENTS.

ILLUSTRATIONS.—Some of the Officers of the American Institute of Mining Engineers—James Douglas, New York, President; Theo D. Rand, Philadelphia, Treasurer; R. P. Rothwell, New York, Board of Managers; R. W. Raymond, New York, Secretary; E. D. Peters, Jr., Dorchester, Mass., Vice-President; L. P. Feustman, Mexico City, Vice-President; A. R. Ledoux, New York, Vice-President, 337. Winnipeg Mine, Wilmington Camp, B. C.; B. C. Mine, Greenwood, B. C.; Mother Lode Mine, Deadwood, B. C., 340. Commemorative Scroll Presented to Returning Soldiers, 341. F. McM. Stanton, Houghton, Mich., Board of Managers; W. C. Ralston, Oakland, Cal.; Arthur Winslow, Kansas City, Mo., Board of Managers; E. H. Benjamin, Oakland, Cal., 342. Latest Mining and Metallurgical Patents, 343. Incline Retarding Conveyor, 349.

EDITORIAL.—The American Institute of Mining Engineers, 337-338.

MINING SUMMARY.—345-346-347.

THE MARKETS.—The Local Markets; Mining Share Market; Sales in San Francisco Stock Board, 366.

MISCELLANEOUS.—Concentrates, 339. Mining in the Boundary District, B. C.; Concentration of Auriferous Sulphides in California, 340. Meeting of the Iron & Steel Institute; A Channel Through the South Pass of the Mississippi River; For the Life-Saving Service; A Commemorative Scroll; Exports of Tin from the Straits to China and India, 341. Not Universally Understood; Entertainment of the American Institute of Mining Engineers; Production of Mines of Grass Valley and Nevada City, Cal., 342. Latest Mining and Metallurgical Patents, 343. Rand Deep Levels, 344. Industrial Notes; Personal; Recently Declared Mining Dividends; Commercial Paragraphs; List of U. S. Patents for Pacific Coast Inventors; Books Received; Catalogues Received, 347-348. Iron and Steel; Incline Retarding Conveyor; Antique Cement Analyzed; Cyanide Prior to Amalgamation, 349. California's Mineral Product and Values for Twelve Years, 352-353.

uable of the numerous contributions to mining literature.

Theodore D. Rand, treasurer of the Institute, is also first vice-president of the Franklin Institute of Philadelphia, Pa.

Richard P. Rothwell, who organized the American Institute of Mining Engineers at Wilkesbarre, Pa., in 1871, is at present one of the Board of Managers. He is known as a successful mining and metallurgical engineer and has wide fame in current technical literature and valuable statistical compilation. He declined the offered first presidency of the Institute, believing that an older man should have it, and proposed Mr. David Thomas, who was elected. In 1882 Mr. Rothwell was elected president of the American Institute of Mining Engineers.

The objects of the American Institute of Mining Engineers are to promote the arts and sciences connected with the economical production of the useful minerals and metals, and also the welfare of those engaged in those industries, by means of meetings for social intercourse and the reading and discussion of professional papers, and to circulate, by publications among its members and associates, the information thus obtained.

The Institute consists of members, honorary members, and associates. The qualification of members and honorary members is that they shall be mining engineers, geologists, metallurgists or chemists, or persons practically engaged in mining, metallurgy or metallurgical engineering. Associates include all persons desirous of being connected with the Institute who shall be elected in accordance with the rules of the Institute.

The council has power to decide on the propriety of communicating to the Institute any papers which may be received. These contributions from the members form an important and valuable feature of the Institute, as they comprise descriptions of methods and practice in every branch of the mining and metallurgical field, geological sketches, ore deposits, etc., and come from all parts of the world. These papers, valuable in themselves, present the experience and most advanced thought of technically educated and practical operators. They often excite discussions which are as valuable as, if not more so than, the original contribution.

The members of the Institute are critical, though not unkindly so, and the discussions, being just and fair, serve to bring out additional facts and to correct any errors which may have previously appeared.

The scope of the work of the Institute is of the broadest character, embracing not only the precious metal industry, but also that of all base metals, coal, and mineral substances of every kind, as well as accurate geological descriptions of regions familiar in the mining world, and of those in the remotest parts of the earth, for the members of the Institute are in every land under the sun, and many of the papers from those far distant lands are interesting and instructive, because of the inaccessibility of the regions of which they treat. Some of these papers have gone into the classics of mining literature, as, for instance, Posepny's contribution on the "Genesis of Ore Deposits."

The metallurgical branch is also represented in every department.

The transactions of the Institute, with the papers contributed by members, form a valuable chronological history of the advancement of the sciences in mining, metallurgy and manufacturing. In them are found much that is valuable in amalgamation, chlorination, cyanide processes, leaching, smelting, roasting and the treatment of ores and minerals of every description by every known process, old or new. Mechanical construction, concentration, electricity, compressed air, all have their representatives in the field of practice and in literature. Methods of mining are an important feature, transportation under every conceivable condition is described and illustrated, and the technical papers on the steel industry are most valuable to the large number engaged in that branch. It is largely by this comparison of methods that such rapid progress has been made by American mining engineers, and there is no doubt that the American Institute of Mining Engineers has done more to raise the great industry of mining and its kindred pursuits out of the rut of "time-honored methods" than anything else, and it has placed the industry where it properly belongs, in the front rank of advancement and improvement. Engineering feats in mining which a few years ago were not considered practicable are now looked upon as commonplace; and old-time methods in metallurgy have given place to newer, better and more comprehensive ideas, resulting in greatly increased capacity, at a reduction in cost which a few years since would have been deemed impossible.

Glancing through the transactions of the Institute published over twenty years ago, some of the contributions of those days, written in the light of the most advanced knowledge of that time, are obsolete or obsolescent; but the comparison illustrates better, perhaps, than anything else the rapid progress being made, and in twenty years from now it is more than likely that the earnest, profound thought of the present day as set forth in the transactions, will seem as interesting as those of two decades ago do now. Yet in these same old contributions are found papers anticipating by more than twenty years the solution of the difficult problems of that day which are now commonplace matters. These papers show clearly the class of men composing the American Institute of Mining Engineers.

It is twenty-eight years since the Institute was organized, and each year there has been held two or more meetings, but in all this time this is the first visit of the Institute west of the Rocky mountains, though many of the members are not strangers to the Pacific coast.

In the early years of the history of the Institute all the meetings were held in Eastern cities, including Dover, Del., Washington, D. C., Wilkesbarre, Pa., Philadelphia, Pa., Pittsburg, Pa., and Virginia Beach, Va. In 1882, for the first time, a meeting was held west of the Mississippi river, when the Institute met in Denver, Colo., in May.

In July, 1887, during which month a meeting was held in Salt Lake and also at Butte, the engineers visited many of the prominent mines in Utah and Montana. Again, in 1896, a meeting was held in Denver, Colo., but until the present they have never come west of the Sierras. The annual meeting of the present year was held in New York City. That the meeting of September, 1899, will prove one of the most profitable, as well as enjoyable, ever held by the Institute there is no doubt, and Californians, appreciating the visit of the distinguished party, have made preparations to receive them with characteristic Western hospitality.

Numerous letters have been received from Eastern members of the Institute, expressing regret at their inability to attend the meeting, and particularly so as it is the first California meeting; but these gentlemen are detained by press of business, the large interests under their care and direction requiring constant attention. While it is regretted that the meeting will be deprived of the presence of some of the foremost workers in the industrial field, it speaks well for the mining industry that their presence is necessary at home.

The visiting members of the Institute will arrive in San Francisco at 8:15 A. M. on the 25th inst. Headquarters will be at the Palace Hotel. The 25th, 26th and 27th will be devoted to the sessions of the Institute. Following is an outline of the programme of the sessions:

Monday, September 25, 1:30 P. M.

Addresses of Welcome

Presidential Address by PRES. JAS DOUGLAS, LL.D., New York City.

The following papers will be presented in abstract by the authors:

"The Origin of the Yosemite Valley, and the Eroding Effect of Glaciers"—PROF. WM. P. BLAKE, Tucson, Ariz.

"Notes on Mining Cable Tests and Physical Tests of California Timbers"—PROF. FRANK SOULE, University of California.

"The Construction of the La Grange Dam"—E. H. BARTON, Sonora, Cal.

The following papers will be presented in print:

"Stoping With Machine Drills"—BERT. THANE, Sumdum Chief Mine, Alaska.

"Deep Mining at the Utica"—J. H. COLLIER, Tesla, Cal.

"Note on Plate Amalgamation"—ALLAN J. CLARK, Lead, South Dakota.

"The Mines and Mill of the Atacama Mineral Co., Ltd., Taltal, Chile"—SYDNEY H. LORAM, Chingford, Essex, England.

"Investigation of Magnetic Ores from Eastern Ontario"—FRED ERICK J. POPE, New York City.

"The Relative Desulphurizing Effect of Lime and Magnesia in the Iron Blast Furnace"—O. R. FOSTER, Brooklyn, New York.

In the evening a grand promenade concert will be given in the Palace Hotel Court. Music by Cassasa's Band.

Tuesday, September 26.

The following will be read in abstract:

"The Electromotive Force of Metals in Cyanide Solutions"—PROF. S. B. CHRISTY, University of California.

"Some Features of the Economic Geology of Russia"—PROF. A. C. LAWSON, University of California.

"The New Alaska-Treadwell Gold Mills"—ROBERT MEIN, Oakland, Cal.

The following papers will be presented in print:

"The Peculiar Ore Deposit of the East Murchison United Gold Mine, Western Australia"—D. P. MITCHELL, Palo Alto, Cal.

"The Occurrence of Tin Ore at Sain Alto, Zacatecas, With Reference to Similar Deposits in San Luis Potosi and Durango, Mexico"—EDWARD HALSE, Colombia, S. A.

"The Copper Deposits of Vancouver Island"—WM. N. BREWER, Victoria, B. C.

"Rock Salt in Louisiana"—A. F. LUCAS, Lafayette, La.

"The Lee Long-Wall Mining Machine—H. FOSTER BAIN, Des Moines, Iowa.

"Natural Coke of the Santa Clara Coal Field, Sonora, Mexico"—E. T. DUMBLE, Houston, Texas.

"Transcontinental Railway Lines"—JAMES DOUGLAS, New York City.

Wednesday, September 27.

The following will be read in abstract:

"Electricity as Applied in California Mining Practice"—PROF. C. L. CORY, University of California.

"The Geology of Arizona"—PROF. THEO. B. COMSTOCK, Los Angeles, Cal.

"Tangential Water Wheels"—W. A. DOBLE, San Francisco, Cal.

The following papers will be read by title:

"Notes on the Independence Mine at Cripple Creek, Colo."—T. A. RICKARD, Denver, Colo.

"Gold Milling at Minas Prietas"—E. R. ABADIE, Torres, Sonora, Mexico.

"Treatment of Oxidized Ores of the Lake View Consols Mine"—J. W. SUTHERLAND, Boulder, Western Australia.

"The Effect of Heat Treatment Upon the Physical Properties and Microstructure of Medium-Carbon Steel"—ROBERT G. MORAE, Jamaica Plain, Mass.

"Peculiar Forms of Native Gold"—GEO. F. KUNZ, New York City.

"The Cement Rocks of Illinois"—J. A. EDE, Spring Valley, Ill.

"The Temperature at Which Certain Ferrous and Calcic Silicates are Formed and the Effect Upon These Temperatures of the Presence of Certain Metallic Oxides"—H. O. HOFFMAN, Boston, Mass.

"Wolframite Deposits in South Dakota"—A. FORSYTHE, Rapid City, South Dakota.

"Nickel-Steel; a Synopsis of Experiment and Opinion"—DAVID H. BROWNE, Cleveland, Ohio.

CONDENSED PROGRAMME.

WEDNESDAY, SEPTEMBER 27.—*Afternoon*—Visit University of California, College of Mines, and Selby Smelting Works. *Evening*—Banquet at Palace Hotel.

THURSDAY, SEPTEMBER 28.—Visit Stanford University, San Jose, and Lick Observatory.

FRIDAY, SEPTEMBER 29.—Visit New Almaden or Del Monte.

SATURDAY, SEPTEMBER 30.—Visit Grass Valley.

SUNDAY, OCTOBER 1.—Visit Nevada City.

MONDAY, OCTOBER 2.—Visit hydraulic mines in Placer County. Lunch at Auburn. *Afternoon*—Visit Sacramento, Capital City of State.

TUESDAY, OCTOBER 3.—Visit Oroville and dredgers.

WEDNESDAY, OCTOBER 4.—Visit Mother Lode at Sutter Creek and Jackson.

THURSDAY, OCTOBER 5.—Visit Mother Lode. Jackson to Valley Springs. Lunch at Gwin mine.

FRIDAY, OCTOBER 6.—Visit Mother Lode region near Jamestown.

SATURDAY, OCTOBER 8.—Start for Yosemite. Yosemite trip occupies four days—October 8, 9, 10, 11. Yosemite party arrive at Los Angeles, Thursday, October 12.

SUNDAY, OCTOBER 8.—Alternate trip: Visit Fresno vineyards and orchards.

MONDAY, OCTOBER 9.—Visit Carpenteria and Summerland. Arrive Santa Barbara.

TUESDAY, OCTOBER 10.—Visit Santa Barbara.

WEDNESDAY, OCTOBER 11.—Visit Los Angeles and Santa Monica.

THURSDAY, OCTOBER 12.—Visit Mount Lowe. Join Yosemite party at Los Angeles. *Evening*—Proceed homeward, through Arizona.

Concentrates.

SOME ONE has truthfully said: "Good mines make good miners."

THE difference between scientific and judicial geology is sometimes a subject for comment.

IT is claimed that the best grades of Missouri and Kansas zinc blende contain 55 to 60% zinc.

ANTIMONY sometimes occurs in metallic state, but usually as the sulphide of the metal (stibnite).

ZINC ORES which contain iron make a poor grade of spelter and is not saleable as a first-class product.

THE Pittsburg Reduction Co., Niagara Falls, N. Y., can answer any and all questions regarding aluminum.

COPPER sulphides, when roasted prior to matting, produce a higher grade of matte than if not previously roasted.

ELECTRICAL DEVELOPMENT in connection with mine work is at its present highest advance in Cripple Creek district, Colo.

BECAUSE an ore deposit is shallow is not a sign that it is without value. Very rich ore is sometimes found in superficial deposits.

IN Kansas calcite concretions of an amber to brown color have been frequently mistaken for zinc blende, which it somewhat resembles.

TURN PLATES made of rolled steel are superior to turntables in mine workings underground, the latter being unwieldy and requiring many repairs.

THE report of the University Geological Survey of Kansas states that the value of the waste dumps of zinc mines in that section exceeds $1,000,000.

UNITED STATES copper mines last year furnished 243,069 metric tons of copper—55.1% of the world's supply. Spain was second with a total of 54,077 tons.

IF the production of the mines of the Transvaal is not interrupted during the remainder of the year the output will reach about $100,000,000 for the year 1899.

"THE highest mine in the United States" is probably that near the summit of the Sierra Blanca, near Garland, Colo. The mine is 14,400 feet above sea level.

DURING the past eight years mines owned by J. R. De Lamar at De Lamar, Nev., have produced $6,323,000, out of which dividends amounting to $2,350,000 have been paid.

IN ventilation of deep mines is recommended an exhaust fan in the upcast shaft, supplemented by electrically driven fans underground and the discharge of rock drills.

ANY stock in any California corporation is assessable. No by-laws of any corporation incorporated therein can waive the right conferred by the State to assess the stock.

THE hoisting engine formerly in use at the Belcher mine, Virginia City, Nev., which is one of the largest in use on the Comstock, has been sold to an Oregon lumber company.

IT is less expensive to send ore out in trains of half a dozen or more cars and haul them back by horse or other power than to send cars out singly each in charge of a trammer.

THE Secretary of the Interior last week decided that a U. S. patent may issue covering both a quartz and a placer claim, reversing the ruling of U. S. General Land Commissioner Best.

AT the intersection of the Galena and Jordan ledges at Bingham, Utah, 100,000 tons of lead-silver ore were taken out in the early history of the camp. These ores sold for $2,000,000.

PYRITIC smelting is a process of reducing sulphide ores in a blast furnace without carbonaceous fuel, the necessary heat being supplied by the burning of the sulphur contained in the ore.

ORES which contain as high as 15% sulphur should be roasted before smelting. This is a matter of judgment on part of the smelter, for ores containing high values in silver lose silver in the roasting process.

NEARLY every city and village in Honduras, Central America, has been built as the result of mining enterprises in the vicinity, which have been carried on there ever since the settlement of the country.

THE capacity of a blast furnace depends largely upon the quantity of fluxes necessary, the fusibility of the ore and the pressure and volume of the blast. A large quantity of fine material lessens the capacity.

RECENT rope tests at the Royal Testing Laboratory at London resulted in the breaking of a wire rope 3⅛ inches in diameter by a pull of about 250 tons, the full strength of the 1080 individual wires being 330 tons.

SOME ores and also mattes are roasted without salt, the silver combining with the sulphur present in the form of sulphate, which is soluble and is leached out with water. This is the principal feature of the Ziervogel process.

GOOD VENTILATION may usually be secured in a shaft by dividing it into two compartments by a tight partition. When steam is available, powder smoke and other gases may quickly be driven from the bottom of the shaft by turning in steam.

A SUBSTANTIAL track may be made of 2x4 scantling set on the narrow edge and faced with strap iron. In some mines a track of this description is used for empty cars going into the chutes, T rail being used on a parallel track for loaded cars going out.

THE recent discovery regarding the "North Star" at the Lick Observatory, Mount Hamilton, Cal., is that the pole star is three suns or "stars," so close (relatively to terrestial observers) as to appear but one, and that they "revolve around each other."

IT is earnestly recommended to every reader of this paper to keep a file for reference. It is usual to receive several inquiries every week regarding subjects that have been fully treated in previous issues, and so many new and deserving topics constantly merit notice that it is not always practicable to repeat what had hitherto been well said. In many cases reference to the indices of the various volumes would readily show just where could be found the very information desired, in extended form.

JUDGE PRATHER of Spokane, Wash., has handed down a decision enjoining Spokane county from collecting or enforcing a tax levied against the stock of the Le Roi M. Co., holding that the property and not the stock is taxable. The mine is at Rossland, B. C.

THE Transvaal, S. A., gold is worth about $18 40 per ounce. The production of the Rand district for the first seven months of '99 aggregated $55,979,437. England wants that country, and will ultimately absorb it. It means "from the Cape to Cairo," and is inevitable.

THE zinc miners are looking forward to a new market for zinc. One of the new usages of spelter which promises to come in favor is the zinc shingle for roofing. Zinc being a non-conductor of heat and cold, makes it more agreeable for one doing business near the roof.

THE cement made by the Jesuit padres, who established Missions in California more than 120 years ago, has never been surpassed in quality by the product of modern time. Portions of some of the old aqueducts made over a century ago are still in fair state of preservation.

SULPHIDE copper ores may be roasted in heaps out of doors, the copper becoming sulphate. This is washed out with water and the metallic copper precipitated on old scrap iron. The copper in waters coming from mines is in the form of sulphate and may be precipitated in this manner.

Tetradymite consists principally of bismuth and tellurium, and sometimes contains sulphur. It carries from 33% to 48% of tellurium, and from 50% to 61% bismuth. It occurs with native gold in foliated scales, and in laminations with gold, chalcopyrite, magnetite and limonite.

PULVERIZED iron ore has been successfully reduced by mixing with coke dust and smelting in reverberatory furnaces. When the surface of the layer of ore becomes red hot it is gathered in balls, called blooms. These are placed in a machine called a squeezer and compressed to solid masses of iron.

MOLYBDENITE has been found in the following California localities: Cosumnes copper mine with copper ores, El Dorado Co.; Speckerman's mine, Fresno Flat, Fresno Co.; Beveridge mine, near Independence, Inyo Co.; Excelsior mine, Nevada Co.; near Campo, San Diego Co.; South Fork of Kings river, forty-five miles northeast of Visalia, Tulare Co.

THERE can be no reason positively assigned for the segregation of minerals of various kinds to different portions of a vein. A theory advanced is that these minerals were deposited at different times, and that the ascending waters from which the minerals found deposited in the veins were derived, at different times carried varying quantities of the several minerals.

IN the Black Hills of South Dakota the silicious (telluride) ores of the Potsdam and Carboniferous formations must contain at least $6.50 per ton to meet expenses when mined and milled privately; but when treated at custom works the value must reach $10 to $12 per ton. In the Archæan schists the free milling gold ores are mined and milled as low as $1.50 per ton.

THE mines of Bingham canyon, Utah, were first worked for carbonate of lead and silver. The operators quit when sulphides of lead, iron and zinc were reached. Subsequent owners took millions from the sulphide lead zone. The present owners believe they will take even a larger amount from the sulphide copper and gold zone, which by former workers was considered valueless.

Where statement is made that "all the subscribed capital will be applied to the purchase and development of the property," it would probably be more conducive to mutual satisfaction were information vouchsafed as to the proportion of such expenditure. While correct as a general statement, yet if .99 of the amount were applied to the purchase, the result might not be wholly satisfactory—to the investors.

THE Gold Mountain mines in San Bernardino Co., Cal., forty-five miles easterly from Victor Station, are at an altitude of 7500 feet above sea level. The ore shoots occur in a heavy quartzite stratum lying unconformably upon crystalline schists and massive granitic rocks, and overlain by limestone where the latter has not been removed by erosion. At the foot of the hill, near the principal mines of the group, is an alkaline lake covering 200 acres.

PROPYLITE is a rock which has been recognized as a distinct species by several writers of note, among them Zirkel and Stache. Later microscopic investigation has resulted in the general opinion that propylite is altered hornblende andesite, in which the hornblende material has penetrated the feldspars during the process of alteration, and the hornblende crystals are found altered to chlorite and epidote. These rocks contain quartz and are also found without it.

So far as known, Professor Tucker of Columbia University recently produced the greatest heat known to man. By means of a specially constructed electrical furnace and current of unusual power temperature was created of sufficient fervency to vaporize steel, hard quartz, and even platinum. The heat obtained was 6500°. Boiling water at sea level means a temperature of 212° Fahrenheit, red hot iron 800°. Steel melts at 3000° and boils like water at 3500°.

ROCK SALT occurs as the result of crystallization of chloride of sodium from a saturated solution in a natural basin or lake. When so found, it is not always pure, but is mixed with other chemical precipitates and mechanical admixtures as clay and sand. Gypsum often occurs as a residual deposit left by the drying up of a body of water. It is not infrequently associated with rock salt deposits. Rock salt is found in the rocks of all ages. The beds in New York State are Silurian. In California salt occurs in Quaternary dry lake beds.

ON the Pacific coast gold is found in beach sands in several counties of California, Oregon and Washington and on the shores of British Columbia and Alaska. In the southern localities many men at various times have worked the sands by devious methods and obtained a small amount of gold—never enough except in a few isolated cases to pay for the expense of fitting up and the labor required. The gold actually exists, and is found associated with layers of black sand, in part magnetic, having been concentrated by the waves and currents.

TRACHITE is a name which covers a wide range of rocks, and, as these graduate from one variety to another, it is difficult sometimes to draw the line between species. The principal constituents are sanidine, oligoclase, hornblende, sometimes augite, magnesian mica, magnetite and some other minerals. Rhyolite is trachite in which a distinct fluidal structure may be seen with aid of the microscope, and contains distinct blebs of quartz. Liparite is a dense variety of rhyolite.

IN an elevator run by water power in an office building the car is moved up and down by means of a separate hydraulic cylinder, which is fed by a supply pipe. As the water is forced into the cylinder from the supply pipe the car is raised. When the operator wishes to lower the car, he pulls the lever which lets the water out of the cylinder and the car sinks with a speed depending upon the rate at which the water is being let out. An accident causing the withdrawal of the pressure in the cylinder will make the water in it run out rapidly and the car will fall.

ARTICLES on the treatment of amalgamated plates in gold mills appeared in the issues of the MINING AND SCIENTIFIC PRESS of Jan. 7th, July 1st and 15th, '99, respectively; also in "Concentrates" Feb. 11th, '99. The addition of small quantities of sodium has a tendency to collect the globules of finely divided quicksilver. The cause of flouring should be ascertained. It may be due to the character of the ore, to grease dropping into the battery from the cams, or to some mineral substance having a deleterious effect on the mercury. Frequent dressing of the plates has a tendency to keep them in better condition.

A WATER BLAST for ventilating a tunnel in Gunnison Co., Colo., is described as follows: The automatic barrel system of ventilation consists of a barrel set in the stream—outside the tunnel—the bottom a few inches below water level and open; a funnel emptying through a 2-inch center into the top of the barrel, and beside the funnel, also inserted into the top of the barrel, the air pipe leading to the tunnel. In this case 4-inch pipe was used. By a flume water is conveyed to the funnel mouth, into which it pours from a drop of about 5 feet. This fall gathers a great deal of air and drives a constant even current to the breast of the tunnel.

SULPHIDE ORES may be roasted either before or after pulverizing, though the results of lump roasting are not as perfect as when the ore has been previously pulverized. When ore requires roasting preliminary to charging in a cupola furnace the difficulty occasioned by feeding finely pulverized ore to the blast furnace is overcome by slagging the pulverized ore in the roasting furnace. For this purpose a long furnace is constructed, the heat increasing as the fire end is approached. The ores must be mixed so as to form a charge which will slag readily. The pasty mass is withdrawn from the furnace into pots, cooled and broken into lumps, in which condition it is charged to the blast furnace.

The Rosario mine, at San Juancito, Honduras, C. A., is a fissure vein cutting metamorphosed and very hard black clay shales and rhyolite. It is a typical illustration of the banded vein usually found in textbooks but which is rarely seen elsewhere. The value of the ore does not appear to be affected by the change in the country rock, being equally rich in either the metamorphic rock or the eruptive. The ores normally consist of the sulphides of iron, copper, zinc and lead with the usual secondary products of their alteration found in the upper portion of the mine. The values are chiefly in silver, though gold also occurs, and in some parts of the mine is more abundant than the silver. The mine is worked through adits many hundred feet in length. It has paid large dividends.

THE determination of "ore in place" by the measurement of its cubic contents should be made with care; 13 cubic feet to the ton only applies to solid quartz rock, which may contain a nominal percentage of sulphide or other heavy mineral. In lead, zinc and other base metal mines this basis of determination is unsafe, as it requires less than 13 cubic feet to make a ton where these heavy ores are abundant. Some oxidized ores are very porous and relatively light. At the Tiptop mine, in the Lava Beds district, San Bernardino Co., Cal., the ores of the upper portion of the mine required more than 20 cubic feet to the ton in place, and much of this ore contained sixty ounces silver per ton. In Calico, in the same county, the gangue of some of the veins is heavy spar and requires much less than 13 feet per ton.

REGARDING driving belts and how to get good working results, it is to be noted that the good drawing of a belt increases with the friction between belt and pulley, and that the belt should surround as large a portion of the pulley as possible; because of this, crossed belts always pull better than open ones; if practicable, open belts should cover about half the pulley. If the circumference of one pulley be very small in proportion to the other, thus allowing the belt to cover only a small portion of the smaller pulley, a sliding of the belt frequently takes place, especially if the distance between the two pulleys be slight. As slow running of the engine makes strong stretching of the belts necessary, a tightening pulley is often placed midway between the two pulleys, so as to avoid repeated resewing; and if a large power is to be transmitted at little velocity, a broader belt should be employed than would be necessary with greater velocity, or two belts made to run one on top of the other.

A QUARTZ MILL, old or new, should have a larger amalgamated plate than 4 feet. Unless the ore is unusually free milling, twice that length is not too much. When starting a new mill, it is customary to run a quantity of rock of ordinary grade first, to get the plates in condition, and then richer ore may be fed. If the plates are in good condition when starting up, and are kept so, there should be no great difference in the saving in a new or an old mill. Success or failure depends largely upon the amalgamator, and not on the mill, if the latter be properly arranged. Of the gold first passing over new plates a certain quantity is always absorbed, as it were, by the plate, and with time this amount becomes considerable. "Sweating" the plates with scalding water is resorted to by some for the purpose of recovering this gold at the time of the monthly clean-up, but it is a reprehensible practice and damages the plate. Moreover, the next run again absorbs about the amount removed by sweating.

Mining in the Boundary District, B. C.

Written for the MINING AND SCIENTIFIC PRESS.

In visiting a few of the mines of the Boundary district, I went from Grand Forks northwesterly to Phœnix, eighteen miles distant. This point is near the summit which forms a watershed between the Kettle River valley at Grand Forks and the Boundary creek at Greenwood. Near Phœnix are such well-developed properties as the Winnipeg, Old Ironsides, Knob Hill, Stemwinder and Brooklyn. Five miles farther to the northwest is the town of Greenwood in the narrow Boundary creek valley. In the vicinity is the Mother Lode mine and others. Greenwood is well built, with good street improvements, and has a population of 2000. Following down the Boundary creek to the international line, ten miles from Greenwood, is Midway, a growing little town on a beautiful site. Twelve miles northeasterly from Greenwood is Summit Camp and the town of Eyholt, near which are the B. C. mine, the Oro Donoro and others.

The Crow's Nest branch of the Canadian Pacific, building through this section, is locally known as the Columbia & Western. This line is complete as far west as Grand Forks and Columbia, with most of the grading done from the latter place to Greenwood. It will doubtless be operating as far west as Greenwood before the end of the year. Spurs are being built to all the mines of note in the section traversed. The farther destination of the line is Midway, Camp McKinney, Penticton and the Pacific coast.

The Winnipeg mine, of which Duncan McIntosh is managing director, is developed by a 325-foot shaft, following the dip of the ledge. There are 1374 feet of drifting on the vein at the 50, 100 and 300-foot

WINNIPEG MINE, WILMINGTON CAMP, B. C.

stations. The ores are an iron and copper sulphide, with values averaging about $30 gold per ton. Above the 100-foot level there are from 6000 to 8000 tons of ore blocked out, with considerable blocked out below this level. The ledge of ore ranges from 2 to 17 feet wide. There are small values in copper and silver. The Winnipeg has been under development since November, 1897.

The Old Ironsides mine, owned and operated by a Canadian company of that name, has two shafts, 200 and 320 feet deep, respectively, which are connected by a 200-foot crosscut at the 200 level. Drifts on this level in opposite directions aggregate 750 feet. A crosscut of the ore body at this level shows it to be 83 feet wide. On the 300-level a 110-foot drift has encountered the same ore body.

The Granby Con. M. & S. Co. own and operate the Victoria, Phœnix, Ætna and Fourth of July. On the Victoria development is being done through the Old Ironsides levels. A drift extends 350 feet into the Victoria grounds, crosscutting 25 feet of good ore.

The Knob Hill, adjoining the Old Ironsides, is being developed through a crosscut tunnel, which cuts the ledge diagonally and is in 650 feet. Drifts on the ledge aggregate 700 feet, with a 140-foot upraise to the surface. All this work, about 1400 feet, is said to be in ore. The Old Ironsides, Granby and Knob Hill companies are all under the general management of Jay P. Graves, with Wm. Yolen Williams as superintendent. As an evidence of the magnitude of the ore bodies on these properties, the width of the ledge at three different points is given as 83, 145 and 220 feet, respectively. The values in the main are gold, with from 2½% to 3% copper. A 10-drill compressor runs the drills in the mines.

In this vicinity there are four or more parallel lodes, consisting of basic eruptive rock, carrying gold-bearing chalcopyrite. The Brooklyn, Idaho, Stemwinder and others belong to the Dominion Copper Co., controlled by McKenzie & Mann, of Montreal and Toronto, and are in charge of Supt. Frank C. Robbins. The first two are on the same ledge. The Idaho is opened by a shaft 250 feet deep and is equipped with hoisting and compressor machinery. The Stemwinder and others are on a different ledge and are well developed.

The B. C. mine, in charge of Supt. John M. Scrafford, comprises eleven claims, 500 acres. The main shaft sinks on the ore body to a depth of 165 feet, with extensive drifting at the 50 and 150-foot levels. The development aggregates about 1000 feet. On the ledge there are ore shoots which average 27 feet wide. The vein is at contact of porphyry and diabase. The ores are similar to those described above, though the values here are chiefly copper, with small amount of gold. The copper runs from 5% to

B. C. MINE, GREENWOOD, B. C.

10%. On the dumps are 3000 tons of first-grade ore, valued at $75 per ton; 8000 tons of second-grade, valued at about $26 per ton. These values are based on smelter tests. The plant is equipped with a steam hoist and air compressor. A hoist and compressor of much larger capacity have been ordered and will be put in place as soon as the railroad is complete to this point. With new hoisting facilities provided the shaft will be sunk to 1000 feet depth. Thirty-five men are employed. There are building accommodations for 100 men. The Oro Donoro, in the same locality, is opened by a 200-foot shaft, in which are good grades of copper and small values in gold.

The Gold Drop, near Phœnix, belongs to Montreal people and is being developed under the direction of Geo. A. Sonneman, consulting engineer, and Stanley Easton, superintendent.

The Mother Lode, near Greenwood, is the most thoroughly developed mine in that locality. This

MOTHER LODE MINE, DEADWOOD, B. C.

property belongs to the British Columbia Copper Co. of New York, represented on the ground by Manager Frederic Keffer. The mine is well equipped with operating machinery, having two 60-H. P. boilers, with feed-water heaters, 10-drill air compressor, sinking pump, electric light plant, hoisting engine (30-inch drum), and other usual accoutrement. The shaft house is built over a two-compartment, vertical shaft, now at a depth of 250 feet.

The ore at 150 feet depth was found of such grade as to admit of profitable treatment, and so far as the workings go, the grade holds the same. At the 200-foot level 600 feet of drifting and crosscutting have been done, disclosing an extensive body of ore. The property is expected to become a shipper as soon as the railroad reaches the Boundary valley. The outcrop of the ledge appears for 1100 feet. The foot wall is limestone and the hanging wall diabase. The three classes of ores are described by Mr. Keffer as follows: "Calcite carrying copper and iron pyrites, with some quartzite present; a silicate of lime, iron, magnesia and alumina, carrying both copper and iron pyrites; an excessively hard magnetic oxide of iron, with silica and copper pyrites." Practically all these ores carry gold, the calcitic and siliceous carrying small silver values. On the 200-foot level galena and zinc blende were found in the calcite gangue. The gold is carried chiefly in the iron pyrites; samples of copper pyrites contained no gold. One sample assayed 15% copper and $16 gold; while another mass of chalcopyrites, with no iron pyrites, assayed 28% copper and only $1.50 gold. Tests have been made which show that a large proportion of the low-grade ores may be concentrated to the saving of at least 95% of the gold contained therein. The company owning this property have decided to erect a smelting plant on Boundary creek.

In the Boundary country, generally, there are a dozen or more air compressors, having a combined capacity of 90 drills. It is estimated that the entire district can begin shipping as high as 600 to 800 tons of ore per day as soon as the railroad shall have been completed to Greenwood. The wages paid in the district are $3.50 per day for machine drillers, $3.50 for hand drillers, $3.00 for muckers, all shifts being eight hours.

The Granby Con. M. & S. Co. are erecting a smelter at Grand Forks and are well under way with the construction. It will be a matting plant.

The mines herein described are typical of the entire district and illustrate their general characteristics and the extent of developments. WASCOTT.

Greenwood, B. C., Sept. 12th, '99.

Concentration of Auriferous Sulphides in California.

Written for the MINING AND SCIENTIFIC PRESS.

The characteristic gold ores of California are highly siliceous, being in most part quartz, though gold also occurs in feldspar, calcite, and in altered igneous rocks and crystalline schists.

It is pre-eminently a free-gold region—that is, the ores are to a great extent free milling and the larger proportion of the gold is obtained by simple amalgamation. In the early history of mining in California no attempt was made to save the sulphide minerals occurring almost universally in these quartz ores, though in some cases the fact that they contained value was recognized, but having no economical means of separating the sulphides from the gangue nor any way to extract the gold if such concentration were made, nothing of consequence was done in the matter for years and millions of dollars were thus wasted, passing away with the tailings which frequently were swept down the canyons and lost forever. In a few instances the tailings were impounded behind restraining dams and reworked in more recent years with profit. Investigation and experiment has also demonstrated that the tailings contain a variable amount of free gold which has not been taken up by the quicksilver. In some instances this is due to the fact that the ore has not been reduced to a sufficiently fine state of division to release the particles of gold from its matrix and consequently not rendered subject to amalgamation. The loss is also due, in part, to a failure of the mercury to take up some fine particles of gold which had been liberated by crushing, but for which no good reason could be assigned.

Recognizing the constant loss of gold in these various ways, millmen and mechanics with inventive genius commenced to experiment on devices for saving these fine but valuable portions of the ore which were escaping. Many devices were tried and the greater number abandoned after a short trial. Old methods, such as bumping tables, shaking tables—rotary machines with vibratory or jerking motion, and an endless number of mechanical contrivances were employed, and out of them has been evolved the several types of concentrating machines now familiar, including the continuous belt machines, shaking tables, etc. Each of these machines has distinct merit and it seems largely a matter of personal preference among millmen when selecting from the numerous machines now in the market. Undoubtedly some of these machines work better on one class of material than on another, and a machine which does good work at one mine may fail to give satisfaction at another where the material to be handled is different.

In running concentrating machines much depends upon the man in charge of the adjustment and operation of the mechanism. Because he has made a success at one mine where the material was pure quartz with iron pyrite and gold, it does not necessarily follow that he can successfully run the same make of machine with the same grade, speed and quantity of water on an ore composed largely of soft schistose material with a larger percentage of sulphurets, which, owing to their crystalline structure, pulverize much finer than at the former place.

It is to this lack of appreciation of a change in conditions requiring a different application, and to the fact that usually no sizing is done, that concentrating machines have been condemned by some men, while receiving praise from others.

It was recognized that the mechanical concentrators would not save all the sulphurets. A machine which would save the coarser sulphides allowed the fine to escape, and one adjusted to save the finest slimes would not save the coarse. It is not to be expected, without sizing, that they would, but the millman of earlier days knowing no remedy, claimed that he was saving 99% and the tailings were valueless.

This state of affairs led to an attempt to save the finer slimes, which were known to be usually higher grade than the coarse material, by some auxiliary process. The outcome of these experiments is the canvas plant, which has come to be considered a necessary auxiliary to gold mills, not only in California, but in many other parts of the world.

The concentration of slimes on an inclined surface covered with canvas is extensively practiced in California, usually with good results, but with many modifications. Some think long, narrow tables are best suited to the requirements and others are of the opinion that broad, short inclines answer the purpose better. That there is any particular advantage in either type is not demonstrated. Some

strips are not more than 12 inches wide, though usually the narrow type of sluice is made of 22-inch canvas, of which an inch is covered on each edge by the binding cleat, making an exposed surface 20 inches wide and 30 to 60 feet in length. The general principle underlying the construction and operation of a slimes plant is to provide sufficient superficial area to treat the quantity of material which must pass over it, and the width and length must be determined with this fact in view.

To illustrate: A plant consisting of two strips, each 20 inches wide and 1000 feet long, would not accommodate the output of a 40-stamp mill, nominally about 100 tons daily; but forty strips of the same width, each 50 feet long, might be found to accomplish the desired concentration of the fine sulphides, amalgam and gold.

For the reasons already given, the size of a slimes plant cannot be arbitrarily fixed, for, having adopted a certain length and width of sluice, similar to one successfully operated at a given mine, a like arrangement at some other mine, where the character of the ore is different, might accomplish good work with a smaller area, while double the size may be required. In one instance all the material, after passing over a well arranged plant of good size, was found to still contain a large percentage of valuable but extremely fine sulphides, and another canvas-covered incline of equal area was constructed, on which the pulp was further concentrated at a profit.

The grade of the table also varies somewhat in the different plants; but, to accomplish good work, the tables must not be overloaded. The method employed is to conduct the pulp from the concentrating machines to a box which extends across the head of the canvas plant. This box is perforated with holes either in the bottom or in the lower portion of the side, which are provided with means for shutting off the flow. The number of holes varies with the width of the sluice. In some plants a diverging spreader is employed to secure uniform distribution over a wide sluice. The pulp is turned on to the inclined surface and permitted to run from thirty minutes to an hour, care being taken that the pulp does not bank up on the canvas. The length of time during which the pulp is allowed to flow is ascertained by testing the tailings leaving the lower end of the sluice. If experiments demonstrate that values are passing over inside of half an hour, the time must be shortened or the pulp must be passed over a second sluice.

At the end of a stated time the pulp is shut off from this sluice, and, to avoid overloading, an equal volume is turned over an extra sluice at the end of the series provided for this purpose. Clear water is run over the sluice until the sand is washed away, when under the clear water the canvas will be seen to have a bronze-colored metallic surface—the concentrated sulphides. An apron is then placed under the lower end of the sluice, to carry the sulphurets over the waste launder into one specially provided for the sulphides, by which they are conducted to the settling tank.

The sulphides are removed from the canvas either by sweeping with brooms while the clear water continues to run, or they are washed down by means of a flat-nozzled hose, with water under pressure. Where water is abundant, the latter is the preferable plan, as it saves the cost of brooms and the wear of canvas. Having removed the sulphides in the manner described, the clear water is shut off and the pulp again turned on to the table. The next section is cleaned in like manner, and so on across the entire series. Operations are so timed in a well regulated plant that by the time the workman has gone across the entire series it is time to clean up the first again. Where the size of the plant precludes this, two or more workmen are employed. The size of plants in California varies greatly. The amount of pulp passing daily over these plants ranges from 5 tons to 500 tons.

W. H. S.

(To be Continued.)

AT the annual meeting of the Iron and Steel Institute, held in Manchester, Eng., in August, a paper of interest was read by Prof. Wiborgh of Stockholm, on the use of finely divided ore obtained by concentrating process. By the introduction of magnetic and other methods of separation, the power of enriching iron ores by the removal of undesirable constituents has been greatly increased, and the waste in working in the case of magnetic minerals considerably diminished. The advantages were, however, largely qualified by the circumstance that the concentrate was usually obtained as a powder, which limited its utility; and, therefore, the question of how much material could be best applied was now becoming of importance. Prof. Wiborgh followed these general statements with the description of a furnace designed by himself for the conversion of pulverulent ores into spongy iron capable of replacing scrap in the open hearth furnace, and it was stated that the process had been tried with a certain amount of success.

BY authority of Act of Congress in 1875, the Government contracted with J. B. Eads, the noted engineer, to maintain for twenty years a channel through the south pass of the Mississippi river for $100,000 a year. By means of jetties, Mr. Eads cleared and maintained a channel 200 feet wide and 26 feet deep, with a central depth of 30 feet. It was also stipulated in the contract that for every day of failure to maintain the required depth and width the contractors were to extend their contract an equal time without extra compensation. The contract has now terminated, but there remains an accumulation of time, due to occasional or temporary failures of the system, equal to one year, when the contractor's estate will receive the final payment.

AT Marquette, Mich., an ordinary 35-foot lifeboat, fitted with a 12 H. P. gas engine, made satisfactory showing for the life saving service. During the drill of the life-savers the boat was rolled over and over, and showed that the presence of the engine in the airtight chamber in no way affected the ability of the boat to right itself. The engine kept running, no matter what position the boat was in. Up to this time lifeboats have had but sails and oars, and it is thought improved motive power will be of utility.

A Commemorative Scroll.

In the ebb and flow of the great tide of war a wave of patriotism swept over this west half of America that sent 10,000 men from the field, the forest and the mine to fight for the flag in the far-off Philippines. San Francisco sent a full regiment, and, glorying in their valor, has raised $60,000 to properly welcome the returning soldiers. A part of such welcome was the presentation, last Saturday, to each Californian of a scroll with an individual record. The committee to which was delegated the task invited competitive designs, and met with success, many meritorious creations being submitted. That of H. R. Hopps, of the California Art Glass Works, 105 Mission St., San Francisco, was selected—a notable distinction. Through the courtesy of Wm. Schroeder, president of the California Art Glass Works, a portrayal of the scroll, as designed by Mr. Hopps, is here presented. The stirring theme has received classic treatment. The stately march of the Roman soldiery when in triumph returning was timed to the resounding cry: "A cuspide corona" (a crown for a spear). This motto has been chosen for the scroll.

COMMEMORATIVE SCROLL PRESENTED TO RETURNING CALIFORNIA SOLDIERS.

To the left is the star-eyed angel of peace; behind her floats the flag that has never known defeat. In her right hand is a spear; in her left the crown she bestows. Scenes of strife by land and sea are grouped around this central figure. The Olympia, a California-built vessel, that carried Dewey and won the fight at Manila, is shown in the upper right-hand corner; the Oregon—another California-built battleship—that smashed Spain at Santiago, is portrayed in the lower left-hand corner. In the lower center is depicted the death of a California soldier, and the repulse of an attack upon an ammunition train. Below are the branching palms of the southern seas, and above the State seal of California.

In the past fifteen months 30,000 soldiers have marched past this office. Among them, rank and file, and officers of all grades, was a large percentage of miners, electricians and engineers, and when the returning flag rounded proudly into port with not a stripe torn nor a star missing, the pæans of triumph that hailed the victors were not too loud to wholly drown the low refrain of grief for the fallen, for in many a miner's home there is a vacant chair.

Meanwhile other States will warmly welcome their returning sons. California so does in the presentation of a bronze medal, and an appropriately engrossed scroll, as herewith depicted, the artistic design for which is deemed worthy of a place herein.

THE exports of tin from the Straits to China and India for the first six months of the present year were only 592 tons, while for the whole of 1898 they amounted to 2551 tons, and for 1897 and 1896 were 3214 tons and 6118 tons respectively, which goes to show that there has been a large falling off in production this year. Statistics published give the total visible supply, exclusive of America, as 12,552 tons, compared with 14,076 tons on the 1st ult., and against 17,855 tons in 1898 and 32,267 tons in 1897. The estimated stock in America is about 3000 tons, and the total afloat for the United States is 4010 tons. The shipments from the Straits during August totaled 3750 tons. The output of tin is not keeping pace with the demand, resulting in a higher price, which has not, as yet, seemed to stimulate production.

Not Universally Understood.

A proffer of $200 for a "write-up" of a mining property shows that the province and purpose of this paper are not wholly understood. The individual offering that amount for a notice of his mine cites the illustrated account of dredging operations in the Boise basin, Idaho, and the illustrated account of the Sumpter, Or., district, in the issues of Aug. 5th and Aug. 19th, as sufficiently illustrative to him that "that sort of thing is done right along," and, because his mine is "just as good as theirs," thinks it strange that his offer was courteously declined.

Several times through the years it has been thought in order to make a few remarks on this subject, and the present instance (not an isolated one, but the latest), affords the opportunity.

The policy of this paper is best exemplified in its proud boast that since its establishment in May, 1860, it has never yet taken a dollar to put anything in or keep anything out of its reading columns. If a statement is believed to be so, it goes in without charge; if it isn't, it stays out. There is no assumption of superiority of any kind in this: it is considered to be the correct principle—that's all. What other papers do or do not do is not pertinent. They do as they think best; so do we. If they are right, then we are wrong; but we have a right to be wrong. We simply do not put in paid "write-ups" of mines, or anything else, in the guise of "reading matter." Our reason is that it would not be fair or just to our subscribers. Thousands of men weekly read this paper; they have a right to belief in what they read: they have that belief: they know that, while this paper may be mistaken—sometimes is—yet it is honestly so, and that it is its honest intent to present all things fairly and truthfully, "unawed by influence or unbribed by gain." That some can not understand or will not believe that this paper does not take payment for such articles, has nothing to do with it. The fact does not depend upon their belief nor upon their ability or inability to understand the spirit that actuates the paper in such course.

Instead of taking pay for such articles, the thing is just the other way—those articles constitute one of our biggest items of expense. We pay for the article, instead of getting paid for it. In the cases cited, as in countless other similar instances, a trusted attache of the paper, conservative and experienced, secured the data, personally wrote the article, got the photos and sent the MSS. His only pay was his regular salary, which, with his traveling expenses, was all at the cost of the office. For instance, in last week's issue was an article on Republic district, Wash., written by one of our traveling correspondents who visited that camp at a special expense to this office of about $75, and who wrote from there the article that appeared on page 312 of the issue of Sept. 16th. That article is probably worth $10,000 to that camp; not a dollar was asked or received. Its value to the paper is the fact that our readers who know that the statement was unbought can rely on it as being a truthful and hence valuable account of existing conditions therein. All that this paper gets is the consciousness of affording anyone who reads what is believed to be correct accounts of interesting mining sections; valuable articles that attract attention to the regions of which they treat and thus prove of ultimate value to the mineral industrial development of this west half of America. That is what this paper is for; not to get a few miserable dollars for a paid "puff" of some locality or individual, but to convey to the mining world a correct portrayal of different sections.

When what is here written was stated to a man who recently made a similar proposition to that referred to in the opening lines of this article, his answer was: "I don't believe it. I think, if it were so, that that is a foolish idea. You might as well take the money; that article that you say cost you so much looks as if you were paid for putting it in. If it is so that you don't or won't take pay for such things, how the devil do you pay your way? What *are* your sources of revenue?"

His phrase might have been more silky, but there was no mistaking what he meant. He had no idea of being insulting; he simply didn't believe that any paper was run on such principles, and his words quoted above were simply his way of expressing such disbelief.

This paper has only two sources of revenue: it is sent postpaid to subscribers for $3 per year; single current numbers are 10 cents each; it sells space to advertisers for so much or so little per inch. That its subscribers are pleased with its course is shown by many unsolicited, weekly, laudatory letters from intelligent, discriminating men whose judgment is good and who admire our course; that its advertising space is in demand is shown by a look through our advertising columns, which are really the newsiest and most interesting part of the paper. Inasmuch as both readers and advertisers are satisfied and the publisher preserves his own self-respect, the paper can afford to ignore such occasional misunderstanding of its province and its purpose as is manifested by the circumstance referred to, and good humoredly notices the matter as illustrative of how mistaken men may be in judging motives and intent, and how different the point of view.

F. McM. STANTON, Houghton, Mich., Board of Managers.

REPORTS of mineral discoveries always create interest, but no discovery has the magic effect produced by the announcement of the discovery of gold. It electrifies men in every walk of life alike, which fact accounts for the cosmopolitan character of the population found in new mining camps.

Entertainment of the American Institute of Mining Engineers.

Arrangements for the entertainment of the American Institute of Mining Engineers while in California were taken up by local members of the Institute, who, acting as a committee, appointed an executive committee, of which W. C. Ralston is chairman and E. H. Benjamin general secretary. This committee includes representative mining men throughout the State, and in each county to be visited by the Institute the committee have made arrangements to receive and entertain the visitors. A reception committee has also been appointed, which includes H. T. Gage, Governor of California, J. D. Phelan, Mayor of San Francisco, and other prominent citizens.

The engravings on this page are those of Arthur Winslow, of Kansas City, Mo., and Frank McM. Stanton, of Houghton, Mich., members of the board of managers of the Institute, and W. C. Ralston and E H. Benjamin, who are the chairman and secretary, respectively, of the local executive committee.

The visitors will be met by the reception committee at Montague, Cal., on the 23rd inst. The first trip will be a visit to Shasta Springs. On the 24th the Keswick copper mines and smelters in Shasta county will be visited and in the evening a reception will be given the Institute by Northern California.

Production of Mines of Grass Valley and Nevada City, Cal.

TO THE EDITOR:—Although gold is widely distributed over the Sierra Nevada, in veins and placers, there are few regions in it which show such a concentration of valuable deposits within so narrowly circumscribed an area as occurs in the districts described below. The mines in the Grass Valley district have been and are especially productive. Next in production follows the Nevada City district, and the Banner Hill district comes third. Statistics for the first decade succeeding the discovery of gold in 1849 are very defective; but it is estimated that the mines in the three districts together have produced $120,000,000 up to the present time. Most of the production of early days came from the placer mines, which were often of extraordinary richness. Of late years the gold from Grass Valley is derived almost exclusively from the quartz mines, while in other districts the placer mines still contribute a small part of the product. Since 1889 the product of Nevada county has been regularly about $2,000,000 per year. Of this, from $1,100,000 to $1,500,000 comes from the areas of these special districts, including the Brunswick area and the smaller mines on Deadman's Flat. Grass Valley and vicinity leads with a production of from $1,000,000 to $1,250,000, while Nevada City and Banner Hill follow with from $400,000 to $800,000. The larger amount of the production from Grass Valley has come from a few prominent mines, such as Eureka-Idaho, Empire, North Star, Omaha, W. Y. O. D., Pennsylvania, Electric and Osborne Hill. In the vicinity of Nevada City the mines west of the town, namely, Providence, Champion, Merrifield, Home, Reward and Mt. Auburn, usually referred to as the "Creek mines," have yielded the largest quota.

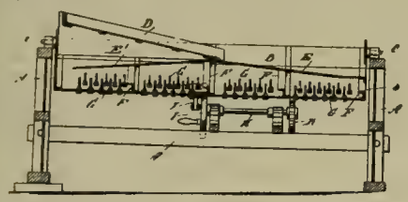
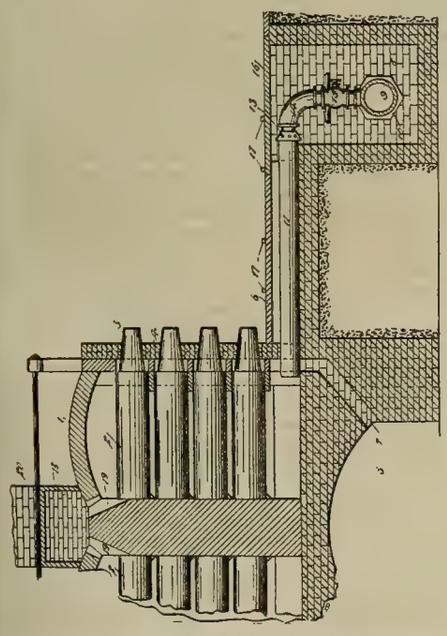
Latest Mining and Metallurgical Patents.

Patents Issued Sept. 12, 1899.



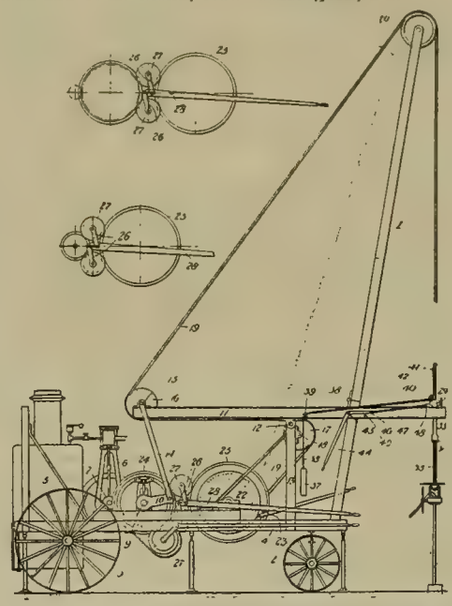
Specially Reported for the MINING AND SCIENTIFIC PRESS.

DUST ARRESTER. — No. 632,370; L. Rossler, Munich, Germany.



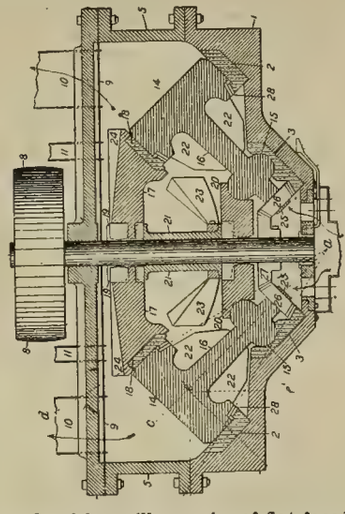
A dust-arresting apparatus comprising a liquid chamber, an inlet pipe having a revolving head in the chamber, a beak c^0 on the head, means for rotating the head, and an outlet pipe. A liquid chamber, an inlet pipe leading thereto, an outlet pipe having enlargements h having conical surfaces, and the plate i with means for raising and lowering the plate.

CONCENTRATOR.—No. 633,059; J. Woodham, Longbeach, Wash.



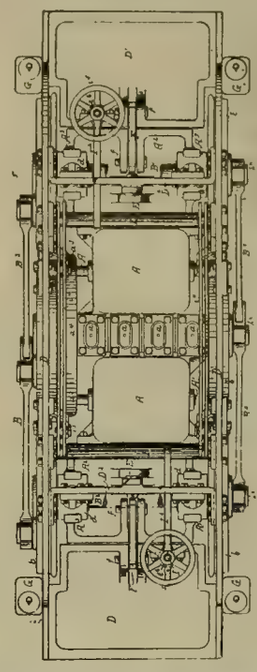
A concentrating device, comprising a semicylindrical trough journaled to oscillate upon its axis and having one end lower than the other and open, inclined aprons carried by the trough and extending from a central point downward toward each end, one apron discharging beyond the lower end and the other terminating short of the upper end of the trough, an inclined screen or grizzly carried by the trough above the upper apron and discharging at the center upon the lower apron, transverse undercut riffles within the trough, stirring pins projecting upward from the trough and means for oscillating the trough.

SMELTING FURNACE.—No. 633,035; J. V. Otten, Iola, Kansas.



A smelting furnace provided with retorts arranged in pairs side by side and in tiers, one retort above the other, a main gas pipe, a controlling valve in gas pipe, burners communicating with gas pipe and extending into the interior of the furnace below the front ends of the retorts, and located in line between the retorts of each pair of tiers, the burners being provided with air inlets, and a flue extending along the upper portion of the furnace adjacent to the rear ends of the retorts and provided with flue openings located between adjacent pairs of tiers of retorts, the flue openings being located at the opposite side of the retorts to that at which the heat is applied. In a zinc smelting furnace, retorts arranged in the furnace in tiers, a flue at the upper part of the furnace and provided with openings located between adjacent pairs of tiers, gas burners extending into a chamber below the retorts and located in line between the retorts of each pair, the burners having shells at their outer ends provided with air inlets whereby the gas under pressure passing through burners will draw in the necessary air, a pipe for receiving gas under pressure, arranged in a subway and provided with a regulating valve, and pipes provided with valves and connecting the shells of the burners with the main gas receiving pipe.

PORTABLE DRILLING MACHINE.—No. 632,921; H. S Glenn and C. E. Glenn, New Kensington, Pa.



In a drilling apparatus, the combination of a main frame; an engine or motor carried thereby; a shaft 9 driven by motor and provided with friction wheel 24; windlass or dum 21 turning upon a shaft or axle in the main frame and provided with friction wheel 25; friction wheels 27 interposed between the friction wheels 24 and 25 and on opposite sides of a line drawn through their axes; and means for drawing the interposed wheels into the spaces between 24 and 25. The wheel 24 having V-shaped periphery; a drum or windlass 21 turning upon a shaft or axle in the main frame and provided with a wheel 25 having V-shaped periphery; friction wheels 27 interposed between wheels 24 and 25 on opposite sides of a line drawn through the axes of wheels, a peripherally grooved to receive the V-shaped edges of wheel; an operating lever 28 pivoted midway between the driving and driven wheels 24 and 25; and links 26 pivoted to the lever at each side of its fulcrum and serving to support and carry the friction wheels 27; the drilling apparatus provided with a double walking-beam and an adjustable tem per screw support mounted therein; temper screw reins pivotally mounted therein; and retracting springs adapted to separate the reins.

PULVERIZING MILL.—No. 632,721; F. G. Johnson, New York, N. Y.

In a pulverizing mill, a series of flat-faced rollers and a series of spheroidal rollers rigidly coupled together two by two by intervening shanks having 45° upward divergency from the horizontal plane and having a series of radial blades, the flat-faced rollers having an annular treadway and a motorplate fitted to revolve on and rotate the rollers and the spheroidal rollers having an annular channel treadway and a motorplate having an annular channel fitted to revolve on and rotate the spheroidal rollers, two motorplates being coupled together by clutch connection with an intervening sleeve having mounted thereon a fanwheel having a series of diagonally upward extending wings turned at right angles upon themselves, in combination with steel dies, a central motorshaft and a suitable inclosing case.

MINE LOCOMOTIVE.—No. 633,064; D. L. Barnes, Chicago, Ill., and W. P. Henszey, Philadelphia, Pa.

The combination in an electric locomotive, of the axles, an electric motor hung to one of the axles, its armature shaft being geared thereto, extensions on the motor, boxes adapted to the extensions and to the axle, a frame resting on the boxes and from which the free end of the motor is suspended. The combination in a mining locomotive, the central axle, wheels thereon, axles at each side of the central axle and having wheels, which are coupled to the central wheels, motors pivoted to the central axle and geared thereto, each motor having an extension, boxes adapted to extensions, platforms at each end of the locomotive and on a line with the motors and their extensions, curved frames secured to the platforms, springs mounted on the boxes and supporting the curved frames and the platforms and suspension rods extending from the frame to the motors.

ORE CONCENTRATOR.—No. 632,892; I. A. Cammett and F. E Shepard, Denver, Colo.

An ore concentrating table having riffles extending from end to end of the active surface of the tables, the riffles being reduced in height toward the foot end, and the reduction in height occurring along an oblique line or area from the feed side to the tailings side of the table and the riffles extending from the head end of the table increased in width toward the foot of the table. An ore concentrator table provided with a series of riffles which are each of a constant height for a portion of their length and of a constant but lower height for a portion of their foot ends.

Rand Deep Levels.

By JOHN YATES, Johannesburg, S. A. R.

NUMBER II—CONCLUDED.

Before proceeding further I should like to touch upon what we may see on these deeper levels regarding the relation of the number of shafts to the number of claims and stamps. The great expenditure, both capital and working costs, which these shafts will entail will compel us to keep their number down to the lowest possible. Now the number of shafts in undisturbed ground is influenced mainly by the requirements of the law, by ventilation, hoisting, underground tramming, the time taken by the men and boys to reach their working places, and capacity for development. The law permits of any property having but one shaft, provided that this is connected up with another, so that as all the deeper levels will ultimately be connected up on one or more of their boundaries they may have but one shaft. Let us see, therefore, whether one of these contemplated 5000-foot shafts is adequate for working (say) 1,000 claims and supplying 400 stamps. Take the 1,000 claims to be a rectangular block extending 11,900 feet horizontally to the dip (to the heat limit) and 5000 feet along the strike. The distance between this shaft and that of an adjoining property similarly laid out would be a little less than a mile, and the longest tramming and drive would be about half a mile. The ultimate length of the incline shaft would be 14,000 feet.

To supply 400 stamps each underground shift would have to number about 2000 men and boys. Allowing 70 cubic feet of air per man per minute and an air velocity in the down take section of the shaft of 1500 feet per minute, I find that a bratticed shaft 38 by 7 feet, inside timber, would serve both as downcast and upcast for the 140,000 cubic feet of air needed per minute. With large fans placed in the intake, both at the bottom of the vertical and at the stations on the incline, with an independent ventilation for each pair of levels by means of supplementary fans, and with a fan on the surface at the upcast, the maintaining through one shaft of an adequate supply of air even at the extreme southern boundary would appear quite feasible. Further, it must be remembered that the securing and maintaining of very liberal ore reserves for 400 stamps would not call for the incline shafts to be down more than 4000 feet below a level connecting the two shafts, and that by the time the full milling stage was reached, in about three and one-half years after cutting the reef, the two shafts would have levels connected (ten) to permit of a joint system of ventilation. The first level would be connected in twenty-seven months after cutting the reef, as against the ten to twelve months of some of the present deeps, and if we can carry on a one-shaft ventilation for the latter period, what difficulty is there in the way of extending it to the former time, more especially seeing that the ventilation will be a mechanical one, and that with fans, etc., there is no very great difference between ventilating a 2000-foot drive and one of half the length.

As showing what can be done in the way of mechanical ventilation, I would cite the St. Gothard tunnel. The length of this tunnel is nine miles, and according to *Engineering*, the number of trains passing through per twenty-four hours is over sixty, yet two fans 16 feet 5 inches diameter (running sixty-five revolutions per minute) placed at one end of the tunnel, were found sufficient to change a natural southern current of two meters per second into a northern one of .75 meter; the fans sent an ample supply of fresh air right through the nine miles of tunnel.

In the matter of development the width of the property influences the capacity of a shaft. Thus with the lateral boundaries 2500 feet distant from the shaft it would take twenty-seven months to connect, driving at the rate of 90 feet per month, and in this time the incline would be sunk 2700 feet at the rate of 100 feet per month. Taking the levels as being 150 feet apart, the number of those unconnected would be limited to eighteen, and the number of development machines to twice this, or thirty-six. Therefore for the development to keep pace with the 400 stamps it would necessitate each machine opening up only 1,700 tons per month, thus allowing an ample margin even on a 3 feet milling width.

I would point out that placing the shafts but 2500 feet apart—like those of the present Angelo Deep—instead of 5000 feet, does not increase the ultimate average monthly development capacity of the property, which is explained by the fact that development must wait on the incline shafts.

The underground trams, I have already pointed out, would have a maximum run to the shaft of about half a mile, a not excessive distance.

Coming now to the important matter of hoisting capacity, with the 38 by 7-foot shaft needed for ventilation, I find that, taking the 5000 feet vertical section first, if this is divided into five 7 by 7-foot compartments—four hoisting and one pumping compartment—that with four ten-ton skips (the same size as in the Red Jacket shaft of the Calumet and Hecla mine, as described by Mr. Seymour) and an average hoisting velocity of 2500 feet per minute, each pair of skips would raise 1400 tons per twelve hours, or 2800 tons (sufficient for 400 stamps, allowing for 30 per cent waste being sorted out) for the four compartments in the same time. By continuing this 37 by 7-foot shaft on the incline to the head limit, and having four winding stages, each of 3500 feet length with ten-ton skips and an average velocity of 1800 feet per minute, the hoisting capacity of the incline would equal that of the vertical, and it will be noticed that by having the skips and velocity stated the hoisting in both vertical and incline is really in duplicate; one pair of compartments could, if necessary, supply the 400 stamps by hoisting the whole twenty-four hours.

The preservation of the shaft timbers in these deep levels is a matter of vital importance, and arrangements should be made for keeping the timber thoroughly wet, this not only effectively preventing dry rot, but doing away with any possibility of fire. It is also advisable that the rising mains of the pumps, both in the vertical and in the incline shafts, should have branches for hose connections for special or emergency service.

In the ordinary course the night shifts would be available for repairing the shaft, and having bins of four days' capacity underground, and of the same capacity on surface, would tide over any stoppage of hoisting which might be reasonably expected.

Mr. Spengel appears to think that the capacity of inclines is very limited. Compared with verticals the speed attainable is less, but, nevertheless, the capacity is much as you make it, and is directly proportional to the velocity, the size of skip, and the number of stages introduced; if, for instance, you substitute two stages for one of similar velocity and size of skip, you double the capacity by really reducing the length of hoist to half the former distance. Thus by dividing a 14,000-foot level into four stages of 3500 feet each, the incline has the same capacity as a single stage of the latter length. With the hoisting system mentioned and four-deck cages in the vertical and coupled skips on the incline, carrying eighty men at a time, the whole shift could be put down in an hour, which is the time it would take to put a 200-stamp shift down the 6000 feet vertical shaft mentioned by Mr. Miller, using four-deck cages carrying thirty-six men. The nearer working places would be reached in a few minutes, and it is of interest to note that if one hour is allowed between shifts for the clearing of fumes, and a man is the last of his shift to descend and the first to ascend, he would still be able to put in seven hours' work on the remotest part of the property—a time quite sufficient for a fair machine man to put down four 5-foot to 6-foot holes in a stope. To put eighty men in a cage might be objected to by some as involving too many lives in any one catastrophe, but if such an argument is to be admitted we must also object to any steamship or train carrying more than (say) a dozen persons for the same reason. The objection applies as much in the one case as the other. Provided that the factor of safety of rope and winding engine is right—and 2½-inch diameter improved plow steel ropes have a safety factor of over eight: one with a ten-ton ore load to lift 5000 feet—there is no reasonable objection to sending down this number of men, or more, in one cage.

From these considerations it is apparent that there is much that might be urged in favor of working everything below 5000 feet vertical through shafts of this depth which do not need stage winding, allotting each shaft 1000 claims and 400 stamps, thus giving the property about twenty-three years milling life on the very moderate basis of a 3-foot milling width. Of course it is likely that there will be isolated cases where circumstances will make it advisable to have the deepest vertical shafts possible, say 7000 or 8000 feet, when, unless the present quality of ropes is improved upon, stage winding in the vertical will have to be resorted to, but even in these instances it is evident that if the heat and payable limit is going to be at 12,000 feet vertical, we will be confronted with the task of sinking and working long inclines merely a degree shorter than those I have been discussing.

So far I have not placed before you the financial aspect of the matter, but I will now review this, and will first take the working costs attending the two methods of winding Mr. Miller instances for the 6000 feet vertical shaft—one a direct hoist and the other a three-stage wind. The capacity of the shaft is taken as he gives it, viz., 1400 tons per day. I find that, with three stages instead of one, the extra cost for wages, stores and coal is about 7d per ton milled, and even allowing for renewing the more costly 6000-foot ropes every two years, there still remains a difference of over 5d per ton milled to speak in favor of a direct wind to this depth—a weighty argument, seeing that it is upon heat and the relation of working expenses to value of reef that the ultimate extent of the workings on this field will depend. The figures set before us in the paper show that the straight shaft is also somewhat less costly to sink and equip. Mr. Miller suggests that for an 8100-foot vertical shaft four-stage winding might be adopted. For this depth I would consider a two-stage wind equally practicable and far preferable on the score of simplicity and economy. It is noticeable that Mr. Seymour, at the last meeting, expressed himself as being favorable to longer stages than those mentioned by Mr. Miller. Coming now to the capital expenditure needed by the shafts of the future, I will take the hypothetical 1000 claims, measuring 5000 feet on the strike by 11,900 feet to the dip, and find how the expenditure is affected by working the whole of this area through a 5000-foot vertical and an incline, as against working it through two vertical shafts—one 5000 feet and the other 9000 feet deep, with inclines. With the first system we would have:

One vertical shaft 5000 feet deep, 38x7 feet inside timber, at say £42 per foot	£210,000
One incline shaft 14,000 feet long, 38x7 feet inside timber, at say £30 per foot	420,000
Total	£630,000

With the second system we have:

One vertical shaft 5000 feet deep, 26 feet by 5 feet 6 inches inside timber, at say £26 per foot	£130,000
One incline shaft 8000 feet long, 26 feet by 5 feet 6 inches inside timber, at say £20 per foot	160,000
One vertical shaft 9000 feet deep, 26 feet by 5 feet 6 inches inside timber, at say £32 per foot	288,000
One incline shaft 6000 feet long, 26 feet by 5 feet 6 inches inside timber, at say £23 per foot	138,000
Total	£716,000

These figures, which are necessarily very rough approximations, are exclusive of the surface and underground power installations and ropes, which would add materially to them, but would not, I think, greatly affect the difference shown. The magnitude of the figures is such as to arrest attention, but dividing the sum by the number of claims gives only about £700 per claim, which compares favorably with the £600 of some of the properties at present working. The enormous sums, however, which will have to be spent on the mines of the future to bring them to their full milling stage—sums of £800,000 to twice that amount—affords food for thought, and inclines one to ask whether it would not be advisable to keep a few capitalists on hand.

If, now, I take a case where the 1000 claims, measuring 5000 feet by 11,900 feet, are given two shafts instead of one, each consisting of a 5000-foot vertical and a 14,000-foot incline, I get:

Two 5000-foot verticals, 26 feet by 5 feet 6 inches inside timber, at say £26 per foot	£260,000
Two 14,000-foot inclines, 26 feet by 5 feet 6 inches inside timber, at say £22 per foot	616,000
Total	£876,000

the capital expenditure being thus increased £246,000, or £246 per claim, a figure which would be considerably augmented by the more expensive power installation needed by the two shafts as compared with the one. Further, the extra shaft would increase working costs by about 3d per ton milled for wages alone. To this would be added extra coal, stores and shaft maintenance.

I quite agree with Mr. Miller in thinking a recovery of 50s per ton would be satisfactory. I believe that developments will enable much less than this to yield a handsome profit. The certainty that the working of the 5000-foot deeps will result in improved mining methods and appliances being discovered is of itself a plea for the postponing for a time of work on deeper zones, and indirectly favors everything below 5000 feet being worked through the 5000-foot verticals. I would here point out that though Mr. Seymour indicated that stage winding in verticals would probably not be unknown on the deeper levels, he also gave it as his opinion that these levels are likely to be opened up and worked by the inclines of the adjoining northern deeps. Whether the saving effected by giving the block of 1000 claims mentioned one shaft only and one mill of 400 stamps is dearly purchased at the cost of the concentration of hoisting, longer headings, levels and shafts to ventilate, the longer underground tramming and the risk of trouble arising from disturbed ground and complicated workings, is a matter upon which there may be difference of opinion, but as this saving amounts in the case of substituting two shafts to over £700,000, and in the case of substituting four shafts (two of them lower deeps) to over £2,000,000 for capital expenditure and working costs connected with the sinking, equipping and working of the shafts—exclusive of interest—during the life of the mine, it is not a point for hasty decision. In these cases it is assumed that the 1000 claims are given one mill of 400 stamps. If, instead of this, two independent ones of 200 stamps each are erected, the capital expenditure per claim and the working costs will be still further increased. But if the magnitute of the interests at stake calls for an excess of caution in the laying out of the work, even at the expense of increased capital charges and working costs, then would not three 5000-foot shafts—one central one of 400-stamp capacity and two side ones each of 200-stamp capacity—placed about 3300 feet apart along the strike, quite suffice for two such properties as are mentioned (each with 400 stamps and 1000 claims) and fully meet the case?

CIRCULATION in big, strong publications costs less per thousand, is worth more per thousand, and has less waste per thousand, than in any small publications.

Mining Summary.

ALASKA.

Wm. McGillivray writes from Cape Nome that men refuse $15 per day, averaging more with rockers on the beach, where for twenty-two miles coarse gold is found at a depth of 3 to 5 feet below the surface.

Skaguay has incorporated her first mining company, under the laws of Washington, to work a molybdenite mine. The new corporation is the White Pass M. & D. Co., having a capital stock of $500,000. Its property consists of a lode of molybdenite 1 foot wide, discovered 1000 feet below the White Pass Railroad tunnel. The molybdenite is found in a mineralized ledge varying from 5 to 8 feet wide, which has been uncovered 800 feet, the ore assaying $53 73 in gold and silver. One of the agents of Vivian & Co., owners of the metal refinery at Swansea, Wales, was at Skaguay five weeks ago and is said to have offered to purchase all the molybdenite that could be delivered at Seattle for his firm, which led to the incorporation of the company.

ARIZONA.

GILA COUNTY.

The smelter at the Old Dominion mine is reported to be turning out 800,000 pounds of copper per month, at a cost of 9 cents per pound, indicating a monthly profit of $68,000.

Globe *Silver Belt*: The mines owned and operated by the Live Oak Copper Co. are seven miles west of Globe. The property has been developing for a year under the management of F. J. Kaldenberg, secretary of the company, and J. Kesser, Supt., and large bodies of sulphide ore are exposed. The company has been shipping to Silver City and El Paso for six months, and shipments will be increased. The two-compartment shaft is down 40 feet, and from 6 feet below the collar has been in 6% copper ore. It is the intention to continue sinking to 200 feet.——Higdon & Haverly, owners of the Black Copper mine, which adjoins the Black Warrior, have been shipping ore all summer. They are sending out two carloads a week.——The Eureka Copper Co. has large bodies of ore near the surface running 10% to 15%. The company will ship ore to Silver City.

YUMA COUNTY.

Yuma *Sun*: Prescott men will begin operations on a placer mining and irrigation scheme on Bill Williams Fork, in the northern part of this county. The stream will supply water for working the beds of gold-bearing gravel and irrigating land in the valleys below.——A. Modesti and F. Avila are making regular shipments of ore from their lead mines in Castle Dome district, twenty-two miles northeast of Gila City. The ore yields a net return of over $1100 per carload. The force of miners will be increased and a hoist will be placed at the main working shaft. There are three shafts on the property; 175 feet, 150 feet and 75 feet respectively. At 200 feet the shafts will be all connected. The ledge is 3 feet wide, almost solid galena. Two carloads a week are being shipped, which is to be increased to a carload per day.——C. L. Josselyn, owner of the Guiding Star group of gold and copper mines in the Copper Mountain district, has let a contract for 100 feet of work on a shaft now 115 feet deep.——The Mariquitta gold mine, eighteen miles southeast of Ehrenburg, owned by Mrs. J. Traves of Los Angeles, is bonded.

CALIFORNIA.

Amador.

A rich strike is reported from the Keystone mine, at Amador City, on the 800 level. This ore was found on the east wall, near which $60,000 was found last year.

Within the past year the Oneida mine, between Sutter Creek and Jackson, has shown great improvement. The main shaft is down to 1900 feet, and the drifts run on the vein at that and higher levels have opened large bodies of pay rock and it has been determined to build a 60-stamp mill. It is reported that the stock of the company will be increased for the purpose of making this improvement.

The new vertical shaft at the Wildman mine in Sutter Creek is sinking at the rate of 60 feet per month.

The mines in Pioneer district, on the East lode, are reported doing well. The ores are high grade and the formation granodiorite.

Sutter Creek *Record*: Sinking at the Lincoln mine is progressing. The shaft is down 1130 feet. The crosscut being run at the 500 level for the west vein is in 100 feet and is near the vein. A drift is also being run north on the east vein and is in 138 feet. This drift is in a mixture of mineralized quartz and slate. It is the intention of the company to install power drills. The first work will be done at the 1200 level, where drifts will be driven north and south on the vein.

Jackson *Republican*: The Vaughn & Kruger mine, south of the Amador Queen No. 1, owned by Champion & Whitford, is to be developed.——The new hoist at the old shaft at the Oneida mine, which is 700 yards from the new shaft, is finished, and unwatering of the old shaft is in progress. O. Reichling is the engineer at the new hoist.——At the Amador Queen No. 2 the tank at the 800 level is finished, and sinking resumed.——At the Central Eureka a station is being cut at the 1500 level. On the 1350 level the north drift is in 200 feet on the vein. Reservoirs are being cut at the 500, 900 and 1300 levels to catch up water. There are 100 tons of rich ore on the dump.

Jackson *Republican*: At the Amador Queen No. 2, near Jackson, rich ore has been found by Supt. Phillips.——At the Central Eureka, near Sutter Creek, a station is being cut at the 1500 level. It is estimated that there is $20,000 worth of ore on the dump, taken out since the clean-up at the Zella mill a few weeks ago.——The Hepburn G. M. Co., owner of the Bellwether mine, at Jackson, resumed work last Monday. Several men under Supt. W. A. Knapp's supervision are repairing the shaft preparatory to sinking.

Butte.

Oroville *Mercury*: At the Magalia mine work in the lower portion of the mine has been discontinued, pipe and tracks have been taken out, and that portion of the mine will be abandoned. Supt. Gassaway states that they had reached the limit of power, the face being 4500 feet from the bottom of the shaft. Mr. Gassaway says that the channel which was followed into the mountain from Little Butte creek, and which developed into the Perschbecker or Magalia mine, was a branch of the main channel. He is taking gravel from the main channel above the point of its intersection with this branch. The mine employs sixty men. The entire working of this mine was illustrated and described at great length and technical detail in the issues of the MINING AND SCIENTIFIC PRESS of April 8th and 15th, '99.——There is activity in gravel mining all over the Magalia ridge. The Bader mine is working steadily. It is reported that the Parry mine is to be opened on a large scale.——At the Big Butte quartz mine, near Nimshew, a 10-stamp mill is running.——There is some talk of the Princess mine being reopened.

Calaveras.

Work at the Ford mine at San Andreas is to be resumed. E. Kane is the foreman in charge. The water will be pumped out and work commenced on the 700 level.

It is reported that H. F. Voget, who has a placer mine on the Mokelumne river at Spanish Bar, three miles above Mokelumne Hill, has arranged with the Standard Electric Co. for electric power to operate his mine.

The new Gwin mill will be completed about Dec. 1st. The old mill will not be shut down, as has been locally reported. The new mill will not be started up until water power is available, as steam power is considered too expensive for hoisting ore. The development will be considerably extended in the meantime.

The Demarest mine, six miles south of San Andreas, has been transferred to G. E. Stickle for $80,400. It is understood he has San Francisco partners in this deal, which extends to 1901.

The Boston mine, two miles northeast of Mokelumne Hill, is to start up. Four hundred thousand dollars has been spent on this property and the shaft is down 1000 feet. It is owned in Boston.

It is reported that the Edna mine, three miles northeast of San Andreas, near Spring gulch, has been bonded to San Francisco parties, who are to begin work Nov. 1st, '99. This property has a shaft 165 feet deep and 1000 feet of drifts and tunnels. It has two veins, one 40 feet wide and another 116 feet wide. The latter is a dyke rock carrying auriferous iron sulphide, with the occurrence of quartz veins within the dyke.

The Paragon, on the Licking Fork, is working twenty men and keeping the 10-stamp mill in operation. Percy Shuman is the chief owner and Supt.

The Lockwood, three miles from West Point, is being pumped out, it is reported preparatory to resuming work.

San Andreas *Citizen*: In the Commodore mine, two miles north of San Andreas, which is being worked under a bond by W. H. Clary Jr., the ledge has been struck in the 180 level and is found to be wide and rich. The same ledge was struck on the upper level.

San Andreas *Prospect*: The hoist at the Big Bonanza mine, south of Angels, is near completion. Fires were started Wednesday and the new engine was given a trial. Sinking will commence, and the main shaft, down 400 feet, will be sunk 200 feet deeper before crosscutting. A mill is to be erected.

Del Norte.

Crescent City *Record*: Returns from the Selby Smelting Co. to operators of the Union copper mine on 21,540 pounds of ore netted $307.95. The ore assayed 19% copper.

Fresno.

Fresno *Republican*: To furnish water for the Coalinga oil fields, the Los Gatos & Oil City Water Co. has been organized. The incorporators are E. O. Miller of Visalia, G. L. Hoxie, J. A. Hanna, W. G. Holland and F. H. Short. The main supply of water will be from White creek. The reservoir will hold 100,000 gallons, which will supply all the well-boring rigs in the Coalinga district.

Inyo.

The final payment of $50,000 on the purchase price of the Ratcliff mines was made to H. C. Ratcliff, former owner of the property, by O. O. Howard Jr., president of the Ratcliff Consolidated Gold Mines, Limited, on the 12th inst. at Los Angeles. The company have recently completed a survey of all their claims and underground workings. The 10-stamp mill is being enlarged to twenty, and the 50-ton cyanide mill increased to 100 tons' daily capacity. The company is running five tunnels, the lower one of which is 800 feet (on the dip of the vein) below the upper, and is developing a large and promising ore body, the last sampling from which showed an average value of $11.60 on a width of 25 feet. The stopes above tunnel No. 1 were last week showing a breast of ore 40 feet in width which assays nearly $30 per ton. The nearest developed mine is at Randsburg, seventy-five miles distant, and there are no precedents to go by as to what the ore bodies will do in depth.

Kern.

Randsburg *Miner*: The Red Dog mill has been crushing ore from the Wedge and Reedly mines the past week. The Reedly ledge averages 3 feet in width and carries good value.——Goler is once more looking up, nearly one-quarter million dollars having been taken from its placer claims. When the Rand was discovered all the residents of that camp went there, and few returned to their former ground. Now there are fifteen men making wages at dry washing in lower Goler. A few days ago Mr. Baker picked up a nugget weighing $41.86. Rich quartz has been found in many places at upper Goler. A. Castro recently found quartz that will mill $60 to the ton. Goler gold is worth $17.60 an ounce.

A new 130 H. P. gasoline hoist has been placed at the new shaft of the Yellow Aster mine.

The Yellow Aster mine, at Randsburg, employs 168 men; wages are from $2.50 to $3.50 per day.

Bakersfield *Californian*: It is reported that C. Whitaker has struck oil on his claim on Cottonwood creek at a depth of 100 feet.

Los Angeles.

On the north ridge of the San Gabriel mountains, ten miles from Acton Station, are a number of gold mines, some of which have development. The veins carry free gold and auriferous iron sulphide. Though so situated that their operation should be successful, little is done with them, for the reason that the owners do not know how to treat the ores, which are not particularly refractory.

Madera.

On the O'Neal ranch and in the granite country of that section are numerous gold-bearing veins which afford encouraging prospects. Some of these mines have been developed superficially and others have considerable development. The Lilly mine, near O'Neals, is a notable example of the latter class. The quartz contains besides free gold, auriferous iron, lead, copper and zinc sulphides.

Mariposa.

Mgr. MacKenzie, the new grant manager, has his headquarters at Princeton, near Mariposa, and is hiring a large number of miners.

The Merced G. M. Co., F. Klepetko chairman, J. H. Vivian Sec'y, has increased the capital stock from 100,000 shares at $15 per share to 150,000 shares at $15 per share.

Mono.

Henry Trevathan recently finished crushing eighty tons of ore in a stamp mill in the Mono Diggings, near Bodie. He did all the work lone-handed.

Bridgeport *Chronicle*: At the Castle Peak mine, 12 miles south of Bridgeport, formerly the Dunderberg, the new tunnel is being pushed by Supt. Kirmeen, and several men have been put on this week. It is said a sawmill will be built for the use of the mine.

Nevada.

(Special Correspondence).—Clark & Brown are reported to have taken out $7000 from a pocket in the Old California ledge at Meadow Lake. Already prospectors are beginning to search for the precious metals and no doubt some will be successful, as there is plenty of good float, and some one will have the patience to trace it up.

The Orion No. 1 mine, near Old Man mountain, has rich streaks of ore going from $100 to $200 per ton in free gold, but it is not high-grade ore the owners are after, although the higher the grade the better. They realize that a large body of ore running $15 to $18 per ton is worth more than the small streaks of high-grade, and they are satisfied with the lower figures.

The Washington mine—being the old Pullman—has fine ore. Some of the decomposed rock is sprinkled with gold. It recalls to mind the ore that Felix Chappelet packed down to the Mohawk mill from there in the early days of the camp.

Meadow Lake, Sept. 17th, '99.

Grass Valley *Union*: Capt. J. W. Morrell of San Jose, Cal., will reopen the Hudson mine in Rough and Ready district, which he has bonded from the owners. San Francisco men are backing the enterprise. There is a stamp mill, hoisting and pumping plant on the property. It has produced between $25,000 and $30,000 to a depth of 184 feet.——The El Dorado mine, on the ranch of H. B. Nichols, has been bonded to a company, at the head of which is W. Goodwin, C. Wickes, T. Van Overhatton, and C. M. Brust. A tunnel 700 feet has been run. The ledge is small, but in places it has been rich.

Placer.

Auburn *Argus*: The new company controlling the Bellevue mine, Ophir district, is making a 36-foot water wheel to replace one of 18 feet. In the mine drifting is progressing on the 200 level. P. S. Lozano is Supt.——The California mine is west of the Bellevue and is owned by F. F. Pellow. Fifty thousand dollars was taken from rock milling $50 to the ton in early days. The property has five veins and a shaft 240 feet deep on the largest ledge.

Auburn *Herald*: At the Jupiter Consolidated the drift up the channel has run out of gravel. The drift down is still in gravel. For the month 120 ounces have been taken out in running the drifts.——W. E. Whitney is working the old Dixon mine at Deadwood.——It is reported that F. Chappelet, Sr., who has examined the Buckeye gravel, considers the lead a part of the old Mayflower channel.——The MacDonald Company have the old Dardanelles slope nearly pumped out.——At the Herman mine, near Last Chance, in the lower tunnel 300 feet below the old works, the ledge has been struck. It is 10 feet wide and runs $15 to $50 per ton. Dr. O. L. Barton is superintendent. The mine has paid well from the outset.

Colfax *Sentinel*: E. M. Armstrong, Supt. Oro and Mountain View mine near Iowa Hill, has bought a three-fourths interest in the Van Riper drift claim. The remaining one-fourth interest is retained by T. Gostlin.——The new mill at the mine of the Dutch Flat Blue Lead is running. A larger force will be put on in the mine as soon as the drifts and shafts can be put in shape.

Auburn *Leader*: The Gold Blossom mine, above Ophir, will resume work the first of October with a full force. J. E. Walsh will superintend.

Sacramento.

M. K. Miller is building a dam to turn the course of the American river to enable him to mine a portion of its bed.

San Diego.

The Pasadena mine is one mile north of the Cargo Muchacho mine and six miles east of Ogilby. The mine has been developed through tunnels and considerable rich ore extracted but little profit realized owing to the expensive manner of handling the material, which was shipped by wagon to the railroad, loose in wagons and thence to the old mill at El Rio, on the Colorado river. Had the ore been worked at the mine it should have paid a good profit. The property is not worked out, however, and under the improved conditions now obtaining in that district a much lower grade of ore will pay.

Shasta.

(Special Correspondence).—H. Oliphant & Son are developing six claims near Harrison gulch. They have three ledges that average 3 feet each and give assay values of 4% copper and $18 gold.

O. LaPlant is shipping ore from his mine near Copley. The ledge is 22 inches wide and the ore yields $16 gold and two ounces silver per ton. He is also shipping ore from a claim near Keswick that yields an average of $35 per ton.

At the Black Diamond copper mines, near Stillwater, extensive development is in progress. Sixty men are employed. This property is controlled by a company of Cologne, Germany, bankers.

Hunter & Fry are developing a group of copper claims near Copper City.

Near Shasta, J. Meier is developing fourteen claims. He makes occasional shipments of high-grade ore from one claim to the Selby Smelting Works.

Shasta, Sept. 18th, '99.

Shasta *Courier*: Engram & Davis are opening a mine south of Shasta, between Middle Creek and Gold Hill. The claim is on the Muchmore property. The ledge runs north and south, and is cut by a tunnel at 125 feet. The owners drifted south on the vein, taking out ore that runs $40 to $60 at the Keswick smelters. The face of the drift is in rich sulphurets. Much free gold can also be seen. Another vein of sulphurets, running north and south, was cut in driving the tunnel. Bunches of free gold quartz are often encountered.

Redding *Free Press*: A mine discovered by J. A. Wilson in the Afterthought country is named the Alta. Mr. Wilson has opened the ledge 20 feet and sunk on the pay. The vein dips at an angle of 45° and is 3 feet wide, carrying free gold all the way, in crystallized quartz, much of it forming beautiful specimens.

Sierra.

The Sierra County Miners' Association holds its annual meeting October 14th to elect officers for the ensuing year and select delegates to the State convention.

Isaac Copeland reports that the water has decreased 200 inches in the North Fork within the last three weeks, due to the extreme heat and hot winds.

E. Brown, representing Ross & Phelps, has taken a bond on the Last Change claim, owned by J. Nipp. The claim adjoins the Magnolia, and both will be worked under one management.

The Bald Mountain extension drift mine, consisting of 1300 acres, through which runs large gold-bearing ancient rivers, is reported bonded to English people. The property is between Downieville and Forest City, 6000 feet above sea level.

Siskiyou.

Yreka *Journal*: During the week M. Schuler of Scott Bar has taken contracts of purchase on the ground on which the town of Scott Bar is situated, and for two miles of river frontage above the town. Through this land runs three channels, reported to be rich. Of these channels, the one nearest Scott river is below the channel of that river. All these channels have been opened in many places and worked by drifts and tunnels, producing heavy, coarse gold.——The company working the Nehrbass ranch, adjoining the Blue Gravel mine, on Greenhorn, has shut down work temporarily, but will resume with a new company. The shaft is down 130 feet, and good prospects obtained. Machinery for pumping and hoisting is required.——The Sheba quartz mine, at Patterson creek, is to have new concentrators, compressed air outfit and other apparatus, which necessitates shutting down operations for a couple of months.——The mines lately located in the Gazelle district, on the headwaters of Willow and Squaw creeks, are attracting attention. The ledges are large.

Yreka *Journal*: Wetzel & Co. are in charge of the Greenhorn Blue Gravel mine, and are working a full force day and night. They will sink a new shaft.—— There is a boom in mining at the Mt. Sterling section of Cottonwood district, near the Oregon line. Rich quartz has been found on the summit of the mountain. At the base of the mountain good placer ground has been discovered and located. There is a scarcity of water at present.

Sonoma.

The prospect for petroleum in the neighborhood of Santa Rosa is to be investigated. It is claimed seepages of oil have been noticed in numerous wells in that part of the county.

Santa Rosa *Democrat*: The quicksilver mine at Cloverdale will soon be in operation again. There are thirty employes in the mine and the force will be increased to 100. A new boiler and other machinery are being put in.

Tulare.

It is reported that a large body of ore has been struck in the 400 level of a claim owned by B. Bailey and others near Visalia. Claims are being filed upon in the surrounding territory.

Tuolumne.

At the Star mine, on Rose creek, development work is being done. A steam plant is

to be placed at the mine, the water supply failing each summer in the past.

In July the Jumper mill ran twenty-three days, crushing 3500 tons of ore, yielding $27,500; from the Golden Rule, east vein, 810 tons of ore were crushed, yielding $4350 on a twenty-nine days' run with ten stamps; from the middle vein 700 tons of ore were crushed in a run of twenty-five days with ten stamps, yielding $1110. The profits for the month of June from these mines are stated to have been $15,720.

United States Marshal Shine has interested several wealthy Chinese merchants of San Francisco in the Republican mine at Jacksonville.

L. H. Bartlett and E. E. Houghton, of Boston, interested in the Draper mine, have recently visited that property, near Soulsbyville. G. F. Dyer is superintendent. A 10-stamp mill will be erected. A 4-foot vein has been uncovered at the bottom of the 300-foot shaft which is heavily sulphureted with free gold in sight.

There are 175 men at work on the Sierra Railroad branch from Jamestown to Angels, near Tuttletown. On the main line track laying has progressed beyond Sonora to within a mile and a half of the Black Oak mine, near Soulsbyville.

Five hundred men have been laid off the past ten days by the mining companies in this county on account of the Tuolumne Water Co.'s supply failing as usual at this time. The Jumper Co. has laid off 145, the Consolidated 130 and the Eagle Shawmut 100. These companies still retain small forces developing new ground, but many of the smaller mines have closed entirely. The electric power company has closed down its plant, and Sonora, Jamestown, Quartz and Stent use coal-oil lamps.

Sonora *Union-Democrat*: Machines in the Republican mine at Jacksonville were stopped Monday and sinking continued by hand drilling, owing to a lack of water to drive the compressors. The shaft is down 350 feet.——The Providence mill, near Carters, which is operated by steam, keeps ten stamps working at night by securing water for the battery from the Grizzly, the mill of which crushes during the day time. ——At the Grizzly the main shaft has passed 600 feet, and sinking is continued by hand, the compressor closing down so that the entire water supply could be used to drive five stamps of the mill. In the bottom of the shaft and in the south drift at the 600-foot level there is a vein 3 to 4 feet wide carrying free gold.

COLORADO.

BOULDER COUNTY.

The Crystal Dream mine near Glenwood, Ward district, has opened a vein of free milling ore, and the shaft will be sunk 150 feet. The ore averages $150 to the ton from the surface. L. G. Orr is Supt.

The Venture Corporation of London has paid $10,000 on the $45,000 for the Kekionga mine of Magnolia. The mine is to be developed.

The upraise to connect the workings of the San Blas, Ward district, with the surface has been completed. It will now be the main working shaft, and a shaft house will be erected and a steam hoist installed.

The Baltimore on Ni Wot hill, Ward district, is being equipped with a new shaft house, steam hoist and a boiler. Everything will be in running order in two weeks.

CLEAR CREEK COUNTY.

Silver Plume *Standard*: During August there were shipped from Silver Plume 105 cars of ore, an increase of 37 cars over the month of July.——The Bellvue-Hudson people have struck rich ore near the junction of the lower crosscut tunnel and the vein. The ore runs 1700 ounces in silver and four to five ounces in gold per ton.

CHAFFEE COUNTY.

The Mary Murphy mine of Buena Vista district, once a silver producer, has opened a body of gold ore. The gold values are now in excess of the silver.

On the eastern slope of the range in Chaffee county several claims located the past season have opened into good ore bodies.

Near Winfield, the Tasmania M. & M. Co. is erecting a pyritic smelter, and expects to have it blown in within thirty days. It will have a capacity of forty tons per day. The smelter will be employed mostly on ores of the company from the Tasmania, Barracouta and the Silverdale group, where there are large bodies of sulphides.

Munroe & Henderson are working a group in Mystery gulch and another on Hope mountain. In the latter is a 4-foot vein of copper and iron sulphides carrying galena. It runs $20 a ton.

GILPIN COUNTY.

The Gunnell G. M. & M. Co. has let a contract for 500 feet of flume to connect with the upper Fullerton mill above Black Hawk. The company is preparing to put its thirty-three slow-drop stamps in operation.

The August shipments from Black Hawk amounted to 380 cars of concentrates and smelting ore, 6840 tons in all.

The Topeka mine will be equipped with new machinery and increase its working force.

At the Enterprise mine on Yankee hill the smelting ore runs $50 to the ton and the mill dirt six ounces to the cord.

Central City *Register-Call*: In cutting a station for a pump at a depth of 425 feet, west of the shaft in the West Notaway mine, a shoot of ore has been discovered.——During the month of August there were shipped from the Cook mine, on Bobtail hill, 4303 tons of mill ore, which produced 95 tons of smelting ore, besides concentrates, showing an increase over the previous month of 828 tons. It shows a daily average shipment of 141 tons. The Cook property is the heaviest shipper in the county, a position to which it has been worked by slow degrees by Mgr. Colvin.

GUNNISON COUNTY.

The Maid of Athens mine, in Mineral Farm Basin, near Tin Cup, which last year made an output of $25,000 worth of ore from grass root shafts, now has ore which averages $25 a ton, smelting returns, in silver and gold. The vein is 7 to 24 feet wide, all ore. Seams of galena occur, carrying 600 to 1300 ounces of silver and 60% lead. The ore shoot has been opened on the apex of the vein along its strike at intervals for a distance of 200 feet. The vein is in porphyry, lime and black shales and is nearly perpendicular.

HINSDALE COUNTY.

The Climax mine on Henson creek has opened into a body of gray copper ore, which is being drifted upon.

LAKE COUNTY.

The A Y & Minnie, operated under lease by Newton & Douglas, is now making an output of 150 tons per day.

The Fanny Rawlings mine of Leadville has produced $200,000 from November, 1898, to April 1, 1899, and paid $20,000 in dividends from the royalties on ore production. The leases expire December 31, when the company will install machinery and deepen the shaft 200 feet.

Leadville *Chronicle*: A discovery of lead ore has been made in a new shaft sunk on the Stone claim, on Rock hill, by F. Peterson and partner. Peterson has a sub-lease from the Vivian M. Co., and the shaft was down 72 feet when a big body of lead was uncovered. The remarkable feature of the find is the large quantity of crystallized cerussite. Two or three bins have been filled with this, besides large quantities of ordinary lead ore. The bin samples average 35% lead, with some silver and an excess of iron. Deposits of cerussite are of frequent occurrence on Rock hill, but this is one of the first discoveries of cerussite made in Leadville in commercially valuable quantities. Heretofore the pieces which have been discovered have found their way to specimen cases.——The Nubian M. Co. is preparing to do development work, and a new surface plant is being erected by Mgr. Schlessinger. The Nubian Co. has leased the Glass-Pendery, Midland and Hidden Treasure lodes and will sink a new shaft.

MINERAL COUNTY.

Creede *Candle*: For the week past the ore shipments from Creede were 3480 tons.——Supt. Rowley of the United mines has retimbered the old shaft down 100 feet.——M. King says by March 1st he will have completed his contract on the Nelson tunnel, when the tunnel will be 10,000 feet long. The Big Kanawah Co. will continue the tunnel to the United mines.——Bachelor No. 1 is working a larger force than at any time during the year, and the property is producing more ore than at any time during the lease. The ore found several weeks back has proven to be continuous.

OURAY COUNTY.

Ouray *Herald*: The Treasury Tunnel & Reduction Co. is composed of Pittsburg capitalists, who have a group of claims in Red Mountain district, 10,500 feet above sea level. They have run a tunnel in a westerly direction to intersect the veins running from Marshal and Virginius basins. Air drills will be put in and the force increased. It is the intention to drive the tunnel 8000 feet. Forty men are employed under Supt. Wihnnerah.

PUEBLO COUNTY.

The Philadelphia Smelting & Refining Co. has been operating since June 14 on an eight-hour basis, the announcement having been made on that date that eight hours for furnace men would be the rule during the hot months; but it is the opinion of Mr. Guggenheim that the men will elect to work twelve hours at the scale of 1893—an advance of 10% on the scale prior to the strike. This is the same scale that is paid by the other valley smelters.

SAN MIGUEL COUNTY.

The Cimarron mine lost by fire last week the compressor plant, engine house, bunk and boarding houses; loss estimated at $20,000.

The Smuggler-Union mine, near Telluride, is putting new concentrating machinery in the mill.

Ophir *Mail*: Forty-two cars of ore were sent to the smelter from Ophir during August.——C. Enderich, owner of the May Queen group, has completed his work on the group. H. G. Gilkerson has surveyed the claims. This group is compact, and several of the veins show good values in gold and silver.——The vein struck two weeks ago by Brewster and Hathaway on the Little Eva group was found by drifting, and was unexpected. The vein carries gold, silver and iron. The ore will be concentrated at the Ilium mill. The tunnel has been driven over 700 feet.——The Lookout tunnel is in 600 feet, and near the vein. This is the second tunnel run by A. Easterday, the owner, the former one being above 600 feet.

SAN JUAN COUNTY.

A rich copper discovery is reported from Sinbad, northeast of the La Sal peaks, near the Colorado line.——J. H. Clark has doubled the force on his tunnel at Gold basin.——The La Sal M. Co. at Paradox will resume operations this mouth. An air compressor has been put in. The company has also secured copper properties near Geyser pass.

Silverton *Standard*: Three thousand tons of ore and concentrates are shipped out of Silverton to the smelters each month.——The Red & Bonita tungsten mine has the largest vein containing that mineral yet found in that part of the country. From two surface diggings there has been mined three cars of ore that will concentrate five into one.——F. Jones has completed a survey for two mill sites and a tram for the Tom Moore mine. One of the sites is below the mine and the other above the town of Eureka. The latter, being the most desirable, was selected, and a mill will at once be erected and a pipe line laid.——The American Mining & Tunnel Co. will build a mill near the Gold King plant in Gladstone. The tunnel driven by this company in Bonita gulch is in 700 feet and nearing the A. P. Hill vein, for which the crosscut was started. In the tunnel four veins of ore have been cut, not previously known to exist, one of which is 14 feet across and said to be good milling ore. The other three veins vary from 12 to 18 inches and are better grade.

SUMMIT COUNTY.

The shipments of ore from the Park City mines the past week were:

	Tons.
Silver King, crude	700
Daly West	490
Ontario	487
Apex	37
Valeo	19
Total	1,033

A diamond drill is to be set up to prospect the formation in Cucumber gulch (the Spaulding district) under the supervision of F. C. Alsdorf of Telluride.

At the Ontario mine the force is being increased. At the mill the rebuilding of the furnace is being hurried, and at the Marsac mill 100 tons of tailings are being run daily.

Breckenridge *Journal*: After a shut down of a year the Jessie mill in Gold Run is again in operation. The North American Gold Dredging Co. are working the property under bond and lease.

TELLER COUNTY.

Victor *Record*: A discovery has been made on the surface of the Hoosier Boy on the south slope of Beacon hill. A vein, thought to be the extension of the Black Belle lead, has been cut and traced a distance of 700 feet through Hoosier Boy ground. Two assays gave 3 58 and .86 ounces respectively. The first across 18 inches and the lower returns on 3 feet of the lead. Samples taken at a depth of 18 feet across 2 feet of mineral went 3.30 ounces gold and 3.70 ounces silver to the ton. ——Crosscutting 400 feet from surface in that portion of the Gold King owned by the International G. M. Co., Supt. Sherburne has cut the vein first opened in the upper workings. He reports 18 inches to 2 feet of pay, which assays $80 to the ton.

Cripple Creek *Times*: At the Walker lease on Vindicator shaft No. 8, Cripple Creek, last Saturday, the explosion of six sticks of powder in the shaft house wrecked the building. Much of the flying debris fell over and into the shaft. The powder had been placed in the shaft house by the shift coming off duty in the morning, and was lying on sacked ore a few feet from the engineer. At 3 o'clock he left the room, when the powder exploded. The explosion was supposed to have been caused by the powder getting warm, causing the glycerine to run.

IDAHO.

BOISE COUNTY

A mining deal has been made on nine claims located on Clear creek, on Miller mountain. The claims were sold by L. M. Johnson and H. Sommercamp of Weiser to E. G. Hathaway, for $46,000. Ten per cent has been paid. During the winter the purchaser, according to the agreement, is to expend $5000 in development. The ledges are from 20 to 30 feet wide and gold is visible in many places. Assays show from $6 to $75 per ton.

BLAINE COUNTY.

Mining about Hailey is reported in good condition. A number of investors have been there recently. The Black Cinder mine is being opened by Mr. McClure, who promoted the Granite mountain, Montana, property in St. Louis. It is reported large bodies of ore have been opened, while pockets are found that run several thousand dollars to the ton.

The Croesus is being worked and is shipping high-grade ore.

IDAHO COUNTY.

Coston Bros. recently made a rich find in Buffalo Hump, the ore carrying more free gold than any yet exposed in the camp. S. Irwin has made a strike south of the Jumbo. Other discoveries have been made during the past month by Colorado parties.

It is reported coal has been discovered on Rapid river by prospectors near Pollock mountain.

SHOSHONE COUNTY.

The Panhandle M. Co. is a new corporation formed to operate the Panhandle group of six claims in Nine Mile gulch, three miles from Wallace. The company's office will be in Wardner, and its officers are: Pres., A. Burch, Supt. Bunker Hill & Sullivan; Sec'y, C. H. Wentz; Treas., G. W. Harris. The company is stocked for 1,000,000 shares of a par value of 10 cents. The development consists of a tunnel in 800 feet with a winze sunk 60 feet which is 360 feet from the tunnel mouth. The vein shows $12 silver and 40% lead. There are four crosscuts off the main tunnel and a raise started in solid ore. The vein is 5 feet wide with neither wall showing. Shipping will begin within sixty days.

MISSOURI.

JASPER COUNTY.

The sale of zinc ore in Joplin district the last two weeks has not been as active as usual, owing to the war between the smelter men and the Zinc Miners' Association. The smelter men claim that the schedule price set by the association a few weeks ago, which price should remain for six months, is an advance over what they can afford to pay for the ore at present prices of spelter. In order to break the association schedule they reported they should seek other fields for their ore. By reducing the purchase of the ore the smelter men hope to create a surplus of zinc ore in the mines, and a scarcity of spelter, with the hope of reducing the price of one and increasing the price of the other. The zinc miners, however, have shut off their night shifts, only working half time, and have not produced a surplus. The facts are the smelters have no ore on hand, and there is very little ore in the bins at the mines.

MONTANA.

LEWIS AND CLARKE COUNTY.

A rich strike is reported in the property of the Standard Mining Co., near the Drum Lummon, at Marysville.

MADISON COUNTY.

Butte *Inter Mountain*: At Rochester F. R. Merk has sold the Watseka mine for $40,000 cash to Butte and Salt Lake capitalists, C. H. Hand of Butte negotiating the deal. The Watseka is one of the old-time producers of Madison county. Water was encountered with depth to such an extent that the pumping machinery was inadequate to handle it, and work was abandoned. Hoge, McCune and others took the property a year ago, and have been sinking a new shaft, which work has been seriously handicapped by water.

SILVER BOW COUNTY.

Last week the uncovering of a rich lead in digging the foundation for a new building at Butte was reported. An effort was made to have the building stopped, but it has been decided to sink the shaft elsewhere. The site has been purchased and mining will commence. The company recently incorporated in Spokane under the name of the Smokehouse Copper M. Co. owns the lead. This company owns nearly all the big leads under the business portion of Butte and is going to explore them.

At the Anaconda mine the boiler plant is to be replaced by a new one, consisting of six marine boilers. They will be of 200-H. P. each, with a pressure of 170 pounds. The gain in power will be over 50%. In place of the smokestacks being torn out there will be a single self-supporting steel stack. It will be 125 feet high. Over the boilers a new steel building will be erected which will be 110x53 feet. The ropehouse has also been enlarged. About 5000 feet of cable are used, 7 inches wide and half an inch thick.

At the lower works of the Anaconda smelter a new matte furnace is being put in, 42 feet 8 inches interior length, 17 feet 4 inches exterior width. Eighteen cars can be put in a single charge and 150 tons of ore per day can be smelted. This is the third and largest put in this year.

NEVADA.

ELKO COUNTY.

Tuscarora *Times-Review*: The new hoisting works at the Young America's new shaft is near completion. The shaft is down 175 feet and sinking. Several small veins have been cut in sinking, but the main ledge is still below.

EUREKA COUNTY.

A rich strike is reported on Adams hill near Eureka, the ore running $130 in gold and about $70 in silver.

Nearly all the ores in Eureka district contain gold. The ores have never been worked extensively except by smelting, and those running less than $40 a ton in precious metals and 18% to 30% lead could not be made to pay by that process.

LYON COUNTY.

Lyon County *Times*: J. H. Rae and G. W. Bennetts have bonded their copper location to John and J. H. Gregory, of Gibson City, Ill., for $10,000. The mine was formerly owned and worked by the Birdsall Co.

Carson *Appeal*: A plant is to be established at the Morgan mill to work the gypsum deposit near the Mound House. Twenty tons of the raw material is awaiting shipment to San Francisco, where the process by which it is to be converted into plaster of paris will be tested.

STOREY COUNTY.

Since the reinstallation of elevator No. 2, which was taken out for repairs recently, the water has gone down rapidly in the C. & C. shaft of the Comstock. The official telegram of the manager to San Francisco is as follows:

VIRGINIA, NEV., Sept. 21, 1899.

To Aug. Waterman, Secretary Comstock Pumping Association, San Francisco: At 6:30 this morning the water was 84 feet 2 inches below the 1950-foot level station. No. 2 elevator has been running continuously. JOS. R. RYAN.

Andrew Charles has found a vein of high-grade copper ore on Cedar hill on ground claimed by the Sierra Nevada M. Co., at Virginia City. Supt. Kyle notified Charles that he was trespassing on the ground of that company, but Charles claims that the ground he is working on was formerly known as the Phil Sheridan.

WASHOE COUNTY.

Reno *Journal*: Several weeks ago, C. D. Burton, L. H. Williams, Capt. Mills and W. G. Caffrey discovered a large cropping seven miles southeast of Reno, that stands 30 feet out of the ground and is 70 feet wide. Assays return $10 a ton in gold. The footwall was also tested in a number of places, and found to carry $1.04 on an average in gold. The hanging wall is limestone. Six claims are located, and the group has been named the Rattlesnake.

WHITE PINE COUNTY.

At Ely the Chainman, Robust and Huntington mills are all running and making money.

New York parties have bought nine copper mines near Ely, and Mr. Bray of Austin has gone with men to commence work.

NEW MEXICO.

BERNALIELO COUNTY.

Santa Fe *New Mexican*: The Lone Star group of mines at Bland has been bought by the Cochiti G. M. Co., owner of the Albemarle. Some time ago O. P. Posey bought from C. Greenwood one-third interest in this property, and the other two-thirds, owned by H. M. McFarlane, of Chicago, has been purchased. The price paid for the two-thirds is said to be $150,000. It is located on the west side of

Pino canon. It has 2000 feet of development. The vein is 25 or 30 feet wide on the surface, and 40 to 93 feet in the lower level. The site for a mill has been selected. The mill will be operated by electric power generated at the company's plant at Madrid.

SANTA FE COUNTY.

Laswell & Walker, prospectors, have bonded their mine near Bear mountain for $30,000. The mine contains corundum and vesuvianite, and it is the intention of the persons holding it to erect a factory thereon for the manufacture of sandpaper.

OREGON.

BAKER COUNTY.

The Bauzette mine, in the Red Boy district, which was lately sold by J. M. Burke of Spokane to Southern capitalists, has been incorporated with H. B. Brannon of Knoxville, Tenn., president; C. J. Johns, vice-president, and H. Armstrong, secretary and treasurer.

Baker City *Republican*: F Clark has bought a half interest in the Humboldt mine from J. C. Martin. The price was not stated. The Humboldt adjoins the Virginia in the Robinsonville district, the ore assaying high. Mrs. Gardner of Baker City owns the other half interest in the mine.

JACKSON COUNTY.

The formalities of the sale of the Ashland mine to the Ontario & Oregon Gold Mines, Ltd., show the consideration to have been $125,000.

UNION COUNTY.

Allen and Younger have struck a rich ore shoot in their claim, the Bonny Blue, three miles south of Sparta on the Powder river slope. It is developed by 180 feet of tunnel and 80-foot vertical shaft. At the bottom of the shaft ore was found, from which $20 in gold to the pan was taken. In conjunction with the rich streak a 2-foot ledge of sulphuretted ore has been found which assays well. The lower tunnel is being driven to tap it.

SOUTH DAKOTA.

LAWBENCE COUNTY.

The Golden Summit mine at Lead City is taking out high-grade wolframite.

At the Durango mine in Lead City the owners are working the old dumps for wolframite and have a large quantity on hand awaiting shipment. The dumps are also being worked for gold, the ore carrying that metal.

Otto Grautz has made a discovery of wolfram rich in gold on the divide between Lead City and Terraville, near the Highland mine of the Homestake group.

TENNESSEE.

POLK COUNTY.

Miners at the Ducktown copper mines are rioting. The men who struck in the Mary mine last week have been joined by union miners from the Carterstown, Isabella and Hiawasse mines. These mines are all owned by the Ducktown Copper & Sulphur Co. A heavy force of guards, armed with Winchesters, are patrolling the property. The mines are all shut down. The strike grew out of the company's refusal to employ union men, and the discharge of men who had joined the federation.

UTAH.

Salt Lake *Tribune*: The records of strikes and dividends from Utah mines this year surpass all prior records in this regard. The investment of Eastern money in Utah mines this year is greater than the aggregate for a decade past. The gold product of Utah mines has gone forward this year by bounds, and already surpasses the gold product of any former entire year. Strikes are of almost daily occurrence, and many of them are of importance. Increased activity throughout the State will show an output in 1899 which will surpass all previous records. This increase will be largely in gold and copper.

JUAB COUNTY.

Mgr. J. T. Hodson of the Tesora at Silver City reports a 4-foot vein of copper ore exposed in the west drift of the 250-foot level of the Tesora. The ore resembles the high-grade copper ore at Bingham. Assays show 45% copper, thirty-one ounces silver and $4.10 in gold.

E. W. Lambkin of Kansas City, Mo., and others are reported negotiating for the properties of the St. Joe M. Co., embracing a dozen claims on the east slope of the mountain and adjoining the Old Telegraph, of the United States Co.

The Utah Con., Sioux Con. and Mammoth No. 2 properties, at Tintic, are to be reopened under direction of D. B. Gillies, former superintendent of the Parrot mines, as general superintendent, with Robt. Grant as general manager.

SALT LAKE COUNTY.

(Special Correspondence).—The New Mammoth cyanide mill at Bingham has started up.

The Bingham Copper & Gold M. Co. are developing the copper-iron ledges of their property in Bingham canyon, which were formerly worked for oxidized ores. The copper-iron sulphide vein is wide and extensively opened. A crosscut tunnel is being run from Bailey gulch, which will cut the vein at 500 feet depth. Col. Heffron states that work will begin soon on a pyritic smelter.

Bingham, Sept. 16th, '99.

The United States M. Co., which recently purchased the Centennial-Eureka in Tintic district for $2,100,000, on a basis of 30,000 shares at $70, has organized a new corporation with 200,000 shares, of which one-half goes to pay for the mine and the balance is placed in the treasury. The 100,000 shares are placed on the market at $25 per share. In consideration of the magnitude of the enterprise and the fact that the purchasers, in addition to the large sum paid for the property, have expended $140,000 in improvements, etc., the price at which the mine is floated is very reasonable, as the owners of this stock will participate in the treasury stock also.

TOOELE COUNTY.

(Special Correspondence). — The Kismet mine, on West Dip, recently put in a hoisting plant, and are sinking from the 400-foot level. Considerable drifting has also been done on the 300 and 400 levels.

The Omaha development continues from a 400-foot shaft. J. B. Williams is now Supt.

In La Cigale lower workings a great deal of talc has been encountered, necessitating additional roasters in the mill. About thirty-two tons of ore per day are being run from the upper levels, which do not require roasting. This property has an 860-foot incline, from which there are 1000 feet of drifts on the fourth level. There are two additional shafts 500 and 400 feet deep, respectively. In the main workings there are raises connecting levels every 100 feet along drifts.

The Daisy mill is being enlarged to 180 tons capacity, by the addition of four leaching tanks. A. Murphy is Supt.

Adjoining the Daisy is the Helvetia group, belonging to a French company, whose interests are in charge of J. D. Spargo. From their 700-foot shaft there are 1000 feet of drifting. The plans are to develop by blocking out the ore before erecting a mill.

Three new furnaces now being put in at the Golden Gate mill, making nine, will increase the mill's capacity to 1000 tons per day. New rolls are also being added. The refining department, which was for some time closed down, has resumed work, turning out fine copper bullion.

The Sacramento is mining and cyaniding 150 tons of ore per day. The cars convey the ore from mine to mill by gravity.

The Mercur mill, now treating 400 tons of ore per day, will soon have its capacity increased to 600 tons.

A new electrically-operated air compressor has been put in at the Mercur mine, the hoisting and drill work being done by compressed air. In the mine there has recently been found a small stratum of base ore, which will require roasting, but for the present the management has decided to defer putting in roasters at the mill on this account. In the lower workings still larger bodies of oxidized ore were recently opened. The 650-foot incline shaft goes through three ledges — the first near the surface, the second 40 feet lower, and the third 100 feet lower than the second. The Lulu, between the Mercur and Sacramento, also belongs to the Mercur company, and treasurer Geo. Dern states that it is now a shipper of high-grade ore, much of it running $30 per ton.

The Little Pittsburg, situate in the Chloride Point section of the district, has about 2000 feet of development, which takes it through the gold and silver formations of the district. Their silver vein forms the foot wall of the gold ledge. The work of drifting on the veins has been commenced. Supt. Harris states that the values thus far encountered are of good grade, and the indications are favorable. WASCOTT.

Mercur, Sept. 13th, '99.

(Special Correspondence).—The Galena King mine, near Stockton, is running a 2000-foot tunnel to cut the present lower workings which were opened through a shaft. The tunnel will strike those workings 500 feet below the surface. A concentration mill has been ordered of the Gates Iron Works for this property. Its capacity will be seventy-five tons per day. The ores are silver-lead, with a small percentage of gold.

Stockton, Sept. 16th, '99.

WASHINGTON.

KING COUNTY.

Seattle *Times*: A new mill for the Golden Tunnel mine is almost completed. The ore being soft, a pulverizer will be used having a capacity of thirty tons a day. There is water power available for 250 tons per day. A thirty-ton aerial tramway will be used, but contracts have been let for one which can carry 250 tons per day. The mine itself is five miles south of Barlny station, between Index and Skykomish. There is an opening into a natural cave 4000 feet above the sea, and the walls, top and bottom, are lined with soft ore, which runs $16 to $500 per ton. This tunnel is 70 feet high and 50 feet wide. The ore runs 1500 feet in the tunnel. The principal vein is 24 feet wide, carrying small streaks of sulphide which yield gold.

OKANOGAN COUNTY.

Spokane *Chronicle*: At the Palmer mountain tunnel 45 feet were made the last ten days in driving the tunnel, and 20 feet in the west drift on the main ledge.

STEVENS COUNTY.

Spokesman-Review: At the Deer Trail No. 2 mine in Cedar canyon, two stopes of rich ore, measuring 100 and 82 feet respectively, are being opened. The former is a foot wide, and the latter from a few inches to 5½ feet of ore. Thirty-five men are employed in and around the mine. Since March of 1898 the company has paid fifteen dividends of $2500 each, besides buying interests in other claims that go to make up its holdings. The profits came from ore extracted from the Deer Trail No. 2 and the Legal Tender, and there is now sacked about fourteen tons taken from the Elephant claim. The vein dips 30 degrees and in places less than this, and is in limestone. The ore contains chloride, bromide and sulphuret of silver, with 5% to 20% lead. It will run in carload lots from $100 to $200 to the ton.

WYOMING.

ALBANY COUNTY.

A new copper district has been discovered twenty-five miles north of Laramie, and the district of Copper Ridge formed by the miners. The discovery was made by ranchmen in the vicinity. The district covers several square miles on the west side of the Black Hills range. The formation of the country is granite, overlaid by sedimentary strata intruded by eruptives. The mineral is found between porphyry and limestone and between hematite and a metamorphic rock. The ore is copper glance, running 40% copper, twenty-two ounces silver and a trace of gold to the ton.

CARBON COUNTY.

It is reported that in the new shaft on the Rudefeha the lead is 22 feet wide. The ore is sulphide of copper running from 15% to 35%. This lead was struck at a depth of 130 feet. It is the intention of the company to sink to 400 feet. The mine is equipped with steam hoists, pumps and air compressors.

FOREIGN.

BRITISH COLUMBIA.

The Black Jack hydraulic mine, near Barkerville, is reported to have cleaned up 400 ounces for the season.

A crosscut in the Morrison mine in Deadwood camp at a depth of 220 feet is 66 feet in length, and has not reached the hanging wall. The ore will average $12 in gold per ton and 36% copper.

Three Americans report they have discovered large copper-gold deposits on the east and on the north forks of Kettle river, fifty miles from Grand Forks. A stampede followed the announcement. The three Americans say they have staked all they can hold.

Spokane *Chronicle*: The double comparment shaft, completed to the 600-level of Le Roi, is being sunk to the 700, and is within 20 feet of the level. A station is being cut at the 900 level in the main shaft. Stoping is in progress on several levels. On the 700 west, owing to the heavy nature of the ground, it is necessary to use hand drills. Twenty-seven machine drills are in operation.——The ore bin for the Lake Shore mine, near Moyie, is finished. A large shoot of ore was struck in the No. 1 tunnel this week.——A water right has been filed by J. C. Drewry on Wilson creek, six miles north of Moyie. The water will run the concentrator which is contemplated.

Spokesman-Review: S. H. Hayes, Supt. of the Camp McKinney Mines, Ltd., reports the mill running sixty-three days, during which time $5340 has been produced. This result was with a 5-stamp battery, and an additional five stamps will be put in operation. The company owns the Granite and Banner properties, adjoining claims on the south slope of Cariboo mountain in Camp McKinney.

MEXICO.

A. R. Norton at Casas Grandes, Mexico, from the Yaqui river country, says there have been two more companies formed for putting machinery in the placer district of the Yaqui river, making four in all. The placer grounds are not especially rich, but they cover hundreds of acres. Along any one of the streams gold can be found.

NORTHWEST TERRITORY.

(Special Correspondence). — Since the discovery of the Dawson region there have been no new strikes of importance, excepting two creeks, each about twenty miles long. The Big Salmon strike proved to be another up-river steamboat boom, and is a fizzle.

One of the two creeks discovered is American creek, a tributary of Seventy-Mile creek. For several seasons this creek was prospected without success, but last winter the pay streak was found, and are now taking out $75 to $100 per day per shovel — that is, the amount of ground a man can pick up and shovel into the sluices in ten hours.

Jack Wade creek is the other stream above referred to. The pay was located there last fall, after having been prospected and abandoned by former locators. It is paying well. On a fractional claim between Nos. 3 and 4 a shaft was sunk 10 feet to bedrock, and $10 to $16 per pan obtained, nearly $500 being gotten from 4 feet square. On No. 7 one man picking and shoveling picked up from the dirt twelve and one-half ounces of gold in thirty minutes, and later, on the same claim, another man picked up two and one-half pounds in half an hour, and a third party picked out $20.20 in twenty minutes. Five men last week took out $1600 in ten hours. Other claims are better. Thirty thousand dollars has been offered for Nos. 13 and 14, and refused. Both American creek and Jack Wade creek are in American territory.

Forty-Mile Post, August 16th, '99.

SOUTH AFRICA.

At the Transvaal diamond mines the original plan of crushing the "blue" as it came from the mine had been abandoned, it having been found that the larger stones were injured in the process. The old system of weathering the matrix, in use at Kimberley and elsewhere, has been adopted, and the ground is said to be pulverizing satisfactorily, so that washing will be possible at an early date. The diamonds found are stated to be of superior quality and size. There are 117,000 loads of "blue" upon the floors, about 50,000 loads of which are ready for washing, and the estimated cost would be covered at 1s 6d to 2s per load for the entire treatment.

Personal.

ELIHU THOMSON'S address is Lynn, Mass.

W. H. FAWCETT is now Supt. Keep Cool mine, Lakeview, Idaho.

SAM'L NEWHOUSE will return from Baden to Salt Lake City, Utah, Oct. 1st.

W. H. KINNON of Denver has charge of the new smelter near Vernal, Utah.

W. L. AUSTIN has left Denver, Colo., on a professional tour through Mexico.

LEO VON ROSENBERG of New York City is examining mines in southern California.

WM. WETMORE'S address is earnestly desired by an Ouray, Colo., correspondent.

PH. DEIDESHEIMER of San Francisco, Cal., is in Nevada county, Cal., examining mines.

BENEDICT CROWELL of Cleveland, O., who had been in the Lake Superior region examining iron ore properties and later in California on similar business, has returned.

EDW. HORNE is the new superintendent of the North Swansea mine, Mammoth, Utah.

N. DANVERS POWER has resigned the management of the Beacon G. M. Co., Australia.

G. H. FOWLER is the newly appointed manager of the Calcifer mine, Chillagoe, Queensland.

COL. J. R. SOUTHWORTH of San Francisco leaves on the 25th for a business trip through Mexico.

PROF. W. L. WATTS is investigating oil lands in San Benito Co., Cal., for San Jose capitalists.

J. P. EVANS, of the Colorado Iron Works Co., is in Arizona putting up a copper furnace at Valverde, near Prescott.

CHAS. G. YALE was this week re-elected for the seventh time secretary San Francisco County Mining Association.

W. C. RALSTON has succeeded F. M. Williams as president and manager of the Bonanza M. Co. at Sonora, Cal.

LIEUT. HERBERT DEAKYNE, U. S. Corps Engineers, has returned to San Francisco from an official visit to Nevada Co., Cal.

E. A. RIX of the Rix Engineering Co., who has charge of the Alaska mine, Sierra City, Cal., has returned to San Francisco.

A. EKMAN, in charge of the California mineral exhibit at the Paris Exposition, is collecting specimens in Nevada county.

SUPT W. A. DENNIS, of the Mountaineer mine, Nevada Co., Cal., has gone to Los Angeles, Cal., for permanent residence.

P. W. GATES, Pres. Gates Iron Works, Chicago, Ill., is in London, Eng., and expects to return to the United States next month.

NORMAN ROWE succeeds R. S. Masson as electrical engineer in the San Francisco office of the Westinghouse Electric and Mfg. Co.

JNO. I. SABIN of San Francisco, president Pacific Coast Telephone Companies, has gone to Europe to note telephone development there.

MR TYLER HENSHAW, of the firm of Henshaw, Bulkley & Co. of San Francisco, Cal., has returned from a business visit to Seattle, Wash.

LEE COCHRANE, with the Mine & Smelter Supply Co., has gone from that company's Salt Lake branch to the one in the city of Mexico.

F. C. VON PETERSDORFF has left the employ of the Ibex M. Co., Leadville, Colo., to accept the management of a mining property in Sonora, Mexico.

C. W. MERRILL, who is putting in a cyanide plant at Marysville, Mont., will, upon its completion, place a similar one at the Homestake, South Dakota.

A. R. C. SELWYN, late Director of the Geological Survey of Canada and of the Geological Survey of Victoria, Australia, is visiting Sumpter, Or., gold mines.

J. A. FERSON, formerly of the Satellite mine at Campo Seco, where he was assayer, is superintendent of the California Copper Smelting Co., at Madera, Cal.

CAPT. A. M. GRANT, the Salt Lake, Utah, representative of the Colorado Iron Works, of Denver, Colo., has returned to his Utah headquarters from a northern visit.

MRS. PHOEBE HEARST of California is credited with intention to erect two of the buildings of the new University of California at Berkeley, Cal., one of these to be for the School of Mines.

H. RIDER HAGGARD, the English novelist, is developing some quartz claims at Atlin, B. C., and is locally credited with the intention to put up "the second largest stamp mill on the American continent."

MR. A. P. BRAYTON, SR, Pres. Pelton Water Wheel Co, San Francisco, Cal., arrives in New York to-day, returning from a successful European business trip, and will be in San Francisco about Oct. 25th.

JOHN HAYS HAMMOND has been appointed consulting engineer for the Mijnpacht Randfontein G. M. Co., Ltd.; Pope Yeatman has been appointed general manager, and J. B. Pitchford consulting mechanical engineer.

H. H. HIRST of the University of California has been appointed by Washington, D. C., authorities as Special Agent National Irrigation Bureau. This is the first step in the work of conservation of the waters of California.

W. A. CARLYSLE, Supt. Le Roi mine, Rossland, B. C., is considering the relinquishment of the $8000 per year salary to accept $20,000 per annum as superintendent of the old Rio Tinto, Spain, mines, from which copper has been extracted with profit for over 1000 years.

RICHARD A. PARKER, consulting engineer of the United States M. Co., at Bingham, Utah, has returned to San Francisco, Cal. Mr. Parker recently spent a month with assistants making an examination of the Centennial-Eureka mine at Tintic and the property has been taken over by the United States M. Co., for $2,100,000.

J. F. WARDNER has returned from Cape Nome and advances the theory that the gold deposits extend out to sea. He says that two miners placed a caisson 120 feet from low tide. The first lot taken out ran from 15 to 50 cents per shovelful. He asserts that similar experiments were tried at a farther distance from tide mark with even better results.

COL GEO. STONE, who has charge of coast railroad work between Elmwood and Surf, Cal., voices the universal complaint as to scarcity of desired labor throughout the coast and says that railroad operations in Santa Barbara county are greatly delayed in consequence of inability to get men. He has made the final payment on the Merrimac, Nevada Co., Cal., mine, of which he is now the owner.

Industrial Notes.

—Kingman, Arizona, has a tax rate of $3.85 on the $100.

—Wyoming's coal mines are producing 22,000 tons per day.

—The Paraffine Paint Co., 116 Battery St., San Francisco, has declared dividend No. 33, of 25 cents per share, payable at the company's office Sept. 29th.

—Figures recently compiled show that over three-quarters of the world's pig iron production is converted into steel. Thirty years ago not over 4% was so used.

—The armor for the battleship Wisconsin, in course of construction at the Union Iron Works, San Francisco, is now arriving, and the vessel will shortly be ready for her builders' trial trip.

—It is stated this week that the Crocker stock holdings in the Southern Pacific and Central Pacific Companies, representing about $13,000,000, have been bought by Speyer & Co., of New York City.

—The American bridge is spanning the rivers of Egypt, Siberia, Japan, China and Peru, and twenty-six American builders have gone to Rangoon, British India, where an American company is building a bridge.

—Kansas City, Mo., has an order for 500,000,000 feet of Southern yellow pine, said to be the largest single order in the history of the lumber trade, for use in the construction of Cecil Rhodes' proposed Cape-to-Cairo road in Africa.

—At Great Falls, Mont., manufacturing and coal mining industries show a monthly payroll of more than $250,000. Copper interests are booming; the annual output of the town was 60,000,000 pounds, and is now being increased.

—A. L. Ledioux, receiver of the Harney Peak M., M. & M. Co., has been authorized to convey to the Burlington & Missouri River Co. the right of way to construct a railway from the Addie mine spur, a distance of seventy-seven miles, to Keystone, S. D.

—The products of the mineral industries of Kansas for 1898 amounted to more than $7,000,000. The output of zinc ore was of the greatest value ever known in the State. The production of coal was valued at $4,000,000, and of salt more than half a million dollars.

—Amador Co., Cal., has appropriated $300 to entertain the visitors of the American Institute of Mining Engineers, who visit that section of California. Tuolumne, Calaveras and other California counties have also appropriated through their Boards of Supervisors similarly.

—The Cascade, Wash., tunnel is finished a distance of 7000 feet, out of 13,000 feet required before the work is complete, and from 500 to 600 men are working day and night. This tunnel will be completed in October, 1900. Its total length will be two and one-half miles.

—Messrs. Woods of Colorado have incorporated the Pike's Peak Electric Power Co. The lines of the company, conduits, transformers, etc., will be located in Fremont, El Paso and Teller counties. Mining and milling will be a branch of the business. The principal office will be in Victor, Colo.

—The Monterey foundry at Monterey, Mexico, employs 235 men regularly. Most of the mechanics are Americans, who receive on an average from $5 to $8 per day in silver. The other laborers are Mexicans, who receive 75 cents to $1 per day. About 1000 tons of pig iron are imported from the United States each year by this company.

—A narrow-gauge railroad is to be built from Phœnix, Arizona, southwesterly via Gila Bend, thence south via the Ajo mines to the territorial line at the town of Quitovaquite—130 miles. Another line is projected from Phœnix to Jerome, thence to the Grand canyon—105 miles. A third line is planned from Phœnix to Globe and Morenci.

—The Sisquoc mines, Santa Barbara Co., Cal., in addition to a high-speed electric light generator, has put in an engine to supply the current for the shop motors, and their crane excavator is also operated electrically. The latter is a large dredger applied to asphalt digging, and its current is supplied by an overhead trolley line. A navy searchlight illuminates the asphalt mine at night.

—This paper has received over 100 personal letters this month from manufacturers in all parts of the country, each one practically saying that not in ten years was the industrial outlook so good, and never before were orders booked so far ahead. In some cases the statement is made that great difficulty is found in getting enough material to keep the men going. So far as iron and steel are concerned there is a present difficulty of that nature on the Pacific Coast.

—U. S. Consul Allen reports that the American gold mines in the northern province of Peng Yang, Korea, are in active operation. The company employs about forty Americans at its mines, which includes the whole district of Woon San, about 1000 square miles. The company works sixty stamps. Nearly 1200 Koreans are employed in and about the mines in various capacities. The concession is upon a payment to the Korean Government of one-fourth of the net proceeds.

—The local telephone company has stretched aluminum wires between The Dalles and Prineville, Oregon. These wires were stretched too tight, and, being susceptible to climatic conditions, contracted and snapped when the weather became cold. Since having been slackened, no difficulty is anticipated. The Snoqualmie falls power transmission plant, which transmits 30,000 H. P. from the falls—a distance of forty-five miles over two lines to Tacoma and Seattle, Wash.—and which uses large aluminum wires, experienced the same difficulty, having miscalculated the coefficient of expansion of these wires, but by slackening them have no difficulty.

—The foreign commerce of the United States in the month of August, '99, is the largest in the history of that month, being nearly 25% higher than those of August of the phenomenal year '98 and 33% higher than the average of August in the years '94, '95 and '96, while for the eight months of the calendar year ending with August they are the highest in our history, reaching $792,595,332, against $778,632,207 in '98, $641,979,330 in '97, and $602,298,472 in '92.

—The iron situation throughout the South is interesting, says the *American Manufacturer*. Many furnaces in the Tennessee and Alabama districts are sold so far ahead that it is impossible for foundrymen and smaller consumers to obtain iron from them at any figure. Most of the furnaces have orders sufficient to consume their full production far into next year. Iron in the Chattanooga and Birmingham districts is selling as high as $18 and $18.50 per ton, and it is freely predicted that $20 iron will be a reality within the next thirty days.

—The British Consul at Mariupol, Russia, says: "There is still a large market in Russia for machinery, machine tools, leather belting, wire ropes, shovels, coke forks, mining and other tools. I prevailed upon some of the local dealers to pass some trial orders for tools from England, but they informed me that English prices were too high, and that they could have bought the same articles from Germany or the United States more cheaply. I am at no loss to account for the American competition, when one takes into consideration the heavy cost of transport, and especially when it must be admitted that the goods are said to be in no way inferior to those of British manufacture."

—"Labor Day" in Minneapolis, Minn., on the 4th inst., started a novel exposition. The skilled workmen of that city opened a labor and industrial exposition after their parade, which is to be representative of the work of the members of the fifty-four local trades unions. The machinery and exhibits are installed in a building 210 feet long. The machinery includes machines for the use of the metal-working and wood-working crafts, who exhibit the various processes by which staple articles in daily use are produced from iron, steel and wood. Others are exhibits of the allied printing trades crafts, in which the process of printing, engraving, lithographing, ruling, book binding, etc., will be shown from the job work to newspaper printing, including artists, engravers and transferers, illustrating preliminary work in lithographing. The exhibit of the electrical workers is also of interest. In lines requiring heavy and cumbersome machinery the exhibits are confined to the manufactured product, including brick making, broom making, stone cutting, etc. About 200 feet of shafting, provided with a 35 H. P. electric dynamo, furnishes motive power for the machinery. The exposition is different in some ways from the present exhibition of the San Francisco Mechanics' Institute.

—J. F. Stevens, chief engineer of the Great Northern, has given out the following information relative to the improvements now in progress on his line: At Minot and Williston, N. D., and Glasgow, Mont., new yards are being built to give 3000 feet of room. New twenty-stall roundhouses are going up at all of the three places, each to cost $25,000, and a new brick freight and passenger depot is being built at Glasgow that will cost $12,000. The entire Montana division of the line, extending from Minot to Blackfoot, is being reballasted, which gives employment to 800 men, six steam shovels and thirty engines and work trains. On this line thirty new steel bridges are being built and 200 others are being filled and fitted with stone culverts. The work this year alone has resulted in the reballasting of 350 or 400 miles of the track, besides the general widening of the grade and cutting out sags, etc. On the line from Blackfoot to Havre, 150 miles long, thirty miles of new roadbed is being built to lighten the grade. Near Blackfoot, Mont., the contract has been let for the construction of two of the largest railroad bridges in America. One of them is 125 feet high and 1800 feet long, and the other (which will be the highest wooden bridge on the continent and probably in the world) will be 214 feet high and has a total length of 1000 feet. This latter is to be at Two Medicine. These bridges will require 2300 tons of steel and will cost from $180,000 to $200,000.

—One man who claims to have outgeneraled the trust, says he was at the head of a small concern making, let us say, car wheels (that's not exactly it, but pretty nearly,) and about a year ago he got a private hint that the other car wheel people were arranging a combine. He said nothing, but immediately communicated with several of the largest consumers and by offering confidentally a reduction of about 15% secured advance orders that would occupy him over two years to fill, running at full capacity. At the price named every wheel would be made at a loss, and his partners were scared. He told them to keep their mouths shut and wait. In a few months the trust was organized according to programme, and one day a bland agent dropped in and offered him a fair price for the plant. He said he didn't care to sell. The trust thereupon proceeded to cut rates, but the little wheel maker did'nt seem to care. Then they made another and much larger cut which was what he was waiting for, and through a third party he instantly placed orders covering all the contracts he had made at a figure that left him a handsome margin of profit. Without suspecting that the large order came from him, the trust people, alarmed at the losses incurred in the freezing out-process, made another and much better offer for his plant, which he promptly accepted. Now the trust has the concern and is running it day and night to make wheels at 25% under actual cost for the man it tried to freeze out. As fast as he gets them he turns them over on his contracts and reaps the intermediate profit, while, needless to say, the trust howls every time it makes a delivery. The little wheel maker says it is great fun to see a trust on the gridiron.

List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey, Strong & Co., Pioneer Patent Solicitors for Pacific Coast.

FOR THE WEEK ENDING SEPTEMBER 12, 1899.

632,829.—HYDRAULIC ELEVATOR—S. L. Berry, S. F.
632,863.—CHILD'S BIB—C. A. Blank, Berkeley, Cal.
632,833.—WAVE MOTOR—W. A. Cheney, Los Angeles, Cal.
632,806.—PASTE BOTTLE—G. P. Cragin, Spokane, Wash.
632,996.—HARNESS BUCKLE—J. A. Gavit, Waitsburg, Wash.
630,840.—CAN BODY FLANGING MACHINE—A. Lotz, S. F.
632,843.—DENTAL FORCEPS—N. B. McGhee, Orange, Cal.
633,023.—SPECTACLES—C. E. Miehle, Riverside, Cal.
633,099.—SAFETY HOOK—W. Miller, Chloride, Ariz.
632,845.—BADGE FASTENER—J. P. Petsch, Los Angeles, Cal.
632,826.—WAVE MOTOR—M B. Rice, Tustin, Cal.
632,856.—ICE CREAM FREEZER—S. Sweeney, Los Angeles, Cal.
632,954.—RIFFLE PLATE—H. Tuttle, Quartz, Cal.
632,797.—BICYCLE—G. Van Horn, High Grove, Cal.
633,059.—CONCENTRATOR—J. Woodham, Long-beach, Wash.

NOTE.—Plain and Certified Copies of U. S. and Foreign patents obtained by Dewey, Strong & Co., by mail or telegraphic order. American and Foreign patents secured, and general patent business transacted with perfect security, at reasonable rates, and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey, Strong & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

CHILD'S BIB.—Chas. A. Blank, Berkeley, Cal. No. 632,863. Dated Sept. 12, 1899. This invention relates to a bib or device which is especially designed to protect the clothing of young children while being fed, the object being to provide a durable, clean, light and easily handled and cleansing device. It consists of a rigid impervious sheet having the upper portion concaved to fit about the neck and the lower portion formed with a receiving roll having an inwardly curved side, the edges of which are turned upwardly to form conductors so as to convey the spilled material into the roll.

CAN BODY FLANGING DEVICE.—A. Lotz, San Francisco, Cal., assignor to F. A. Robbins, same place. No. 632,840. Dated Sept. 12, 1899. This invention relates to an apparatus for flanging can bodies. It consists in a mechanism by which the end flanges of the can bodies are turned outwardly, and comprises a chuck having a shouldered portion of diameter equal to the interior of the can, a similarly shaped independent ring, the contiguous face of which is coincident with that of the shoulder yielding supports by which the ring is normally retained in line with the shouldered portion. A roller is adapted to be brought into contact with the exterior of the can which is fitted over the ring and shouldered portion, and by suitable mechanism the parts are rotated so that the roller will force the ring out of line with the shoulder portion and thus turn a flange upon the can end; the yielding portion, being made of rubber or similar material, allows for these parts being forced out of line for the above purpose.

Book Notices.

"*Aaron's Assaying*," Parts II and III, third edition, rewritten and revised; printed from new type, in convenient form, and reduced in price to $1.50, postpaid; out to-day; a fine edition of this favorite work, the standard on the subjects of which it treats; 170 pages, octavo; published by the Mining and Scientific Press, 330 Market St., San Francisco, Cal.

"*El Territorio de la Baja California, ilustrada, Mexico*"—the Territory of Lower California, Mexico, illustrated—is the title of an unusually fine folio written and compiled by J. R. Southworth, 23 First street, San Francisco, Cal., descriptive of the resources of Lower California: its agricultural, commercial, mining and other industries. It is official; the statistics and much of the matter are furnished by the Government, and are authentic. Great care has been taken by Col. Southworth to have the work reliable, and for the first time in the world's history appears a comprehensive and elaborate account of the Lower Californian peninsula, extending from 23° to 32° 30′ N. Lat. It is a region that deserves intelligent attention, and the subject is admirably arranged. The typographical excellence of the work is also worthy of notice, the large volume being an edition de luxe. It is printed in Spanish and English, magnificently illustrated, and will undoubtedly direct attention to that Territory. A fine map—the first really authentic one of the kind—accompanies the work, correctly depicting the entire peninsula. The work complete will be sent postpaid, superbly bound, by J. R. Southworth, 21-23 First St., San Francisco, on receipt of $2.50; or, in paper covers, $1.50.

Commercial Paragraphs.

FLINT & LOMAX, electricians of Denver, Colo., have moved into larger quarters at 1939-1943 Curtis street.

J. GEORGE LEYNER, machinist of Denver, sold seven air compressors last week, which went into various parts of the West.

SINCE last June, the Colorado Iron Works Co., Denver, Colo., have received orders for eleven blast furnaces, two of which go to Arizona, five to Mexico, two to Colorado, one to Utah.

L. PETERSON, the pioneer manufacturer of experimental machinery and inventors' models, has removed from his old quarters, 226 Market St., San Francisco, Cal., to 544a Mission St., between First and Second, San Francisco, where he has increased facilities for work.

THE Jackson Drill & Manufacturing Co., 1756 Larimer street, Denver, Colo., H. F. Crippen manager, report the following sales: The Markeen Copper Co., Clifton, Arizona; Nodolgo, Dressel & Co., Monterey, Mexico; S. B. Wilson, Ohio City, Colorado; Black River Mining Co., Ironton, Missouri; Baxter & Kearns, Walsenburg, Colorado; British American Gold Mining & Trading Co., for Buster mines, near Prescott, Arizona.

THE Denver Branch of the Jeanesville Iron Works Co., A. Middlebrook, Mgr., reports recent sales of two electric power-driven sinking mine pumps for Mexico; two large station pumps for coal mines in Colorado; one station pump, 700-foot lift, and No. 7 sinker, for Salt Lake; the factory shipped direct to the Le Roi Co. at Rossland, B. C., three compounds, August 31st, and a compound condensing pump, 1000 gallons capacity, to S. E. Missouri. They have an order for one 16 in. and 30 in. by 14 in. by 48 in., and one 16 in. and 30 in. by 14 in. by 36 in. compound condensing pump, with condenser, to an iron and steel company in the East—the fourth order for this class of pumps from the same company.

IN the issue of the 2nd inst. some reference was made to the action of Judge Hallett in the roasting furnace controversy, and his conclusions were published. The Parke & Lacy Co., 21 and 23 Fremont street, San Francisco, representing the Ropp furnace, has issued a pamphlet in answer to Fraser & Chalmers concerning the matter, which they will be pleased to send to any one interested in the controversy. It is illustrated with cuts of the Brown furnace, the George, Ropp, O'Harra & Allen furnaces, graphically depicting the difference, and concludes with the statement: "We are building the ROPP FURNACES, and will continue to build them. We will stand between our customers and secure them from any loss or damage from any action brought by Brown or others, based upon Brown's patent or patents."

Recently Declared Mining Dividends.

American Zinc, Lead & Smelting Co., $1 per share; payable Oct. 2nd.

Deer Trail No. 2 M. Co., Washington, dividend No. 16, $2500; payable Sept. 25th. Total, $40,000.

Bonanza M. Co., Washington, $2500; Sept. 20th.

New Idria, San Benito Co., Cal., 10 cents and extra 20 cents per share; payable Oct. 2nd.

Napa Con., Cal., 10 cents and extra 20 cents per share: payable Oct. 2nd.

Boston Quicksilver Co., Cal., 10 cents per share; payable Oct. 2nd.

Ætna Quicksilver Co., Cal., 10 cents and 5 cents extra; payable Oct. 2nd.

Isabella M. Co., Cripple Creek, Colo., $22,500; Sept. 20th. Total, $472,500.

New York & Honduras Rosario Co., San Juancito, Honduras, $15,000; Sept. 20th.

Raven M. Co., B. C., $10,000; Sept. 20th.

Santa Rosalia, Mexico, 5 cents per share; payable Sept. 25th.

Champion M. Co, Nevada City, Cal., 49th dividend, 25 cents per share; Sept. 23rd.

Boston-Aurora Zinc M. Co., regular monthly dividend, two-thirds of 1%; payable Sept. 25th.

Homestake M. Co., 25 cents per share; payable Sept. 25th; also extra dividend of 25 cents; payable at the same time.

Petro M. Co., Utah, $5000; payable Sept. 30th.

Catalogues Received.

CATALOGUE No. 3, fourth edition, of Fraser & Chalmers, Chicago and London, is a 170-page octavo treating of roasting, smelting and refining machinery. Amid much that is new and all that is good is noted a technical treatise on lead refining, and a sectional view of a modern refinery. Circular No. 99, of simultaneous issue, is devoted to "Increased Milling Capacity," a statement of a method designed to increase the capacity of existing stamp mills. Either or both of the above will be sent from the Chicago office on request.

CATALOGUE No. 8, of Fraser & Chalmers of Chicago, in the usual complete style of that firm, treats exhaustively of crushers and pulverizers. Considerable prominence is given to the testimonials from users of the Comet crusher, an appliance that is thoroughly illustrated and explained in detail. The treatise will be sent free on request.

A TWENTY-FOUR-PAGE descriptive catalogue of the Mogul draught springs and special high-grade steel coiled springs for all purposes, with illustrated description, classification, tables of weights and sizes, directions for attachment, testimonials from numerous mining companies, practical points on a practical subject: The Wilson Manufacturing Co., 147-149 Cedar St., New York City.

Iron and Steel.

Tests recently made upon Swedish iron and steel show that when the steel contains less than 0.90% of carbon it can be welded and hammered up to 900° C. When it contains 1.10% it can be welded with borax and hammered at 850° C.; 1.30% can only be welded with difficulty and hammered at 800° C. When the carbon is as high as 1.50 the steel cannot be welded at all and cannot be hammered at a higher temperature than 750° C. The purposes for which such steel is suitable are as follows: 0.10% to 0.30%, for carriage axles and strong machinery parts; 0.15% to 0.30%, for boiler tubes; 0.30% to 0.50%, for springs hardened in water; 0 75% to 0.90%, for tubes; 0 45% to 0.60%, for hardened wire; 0 50% to 0.75%, for spiral springs; 0.90% to 1%, for surgical knives and circular saws; 1% to 1.10%, for hand saws; 0 60% to 0.90%, for cabinet-makers' tools, cold chisels and axes; 1% to 1.20%, for cutters' drills, etc.; 1.20% to 1.40%, for turning and planing steel; 1.35% to 1.50%, for scrapers and special tools.

The Demenge process of hardening steel ingots, which is in use at one of the principal steel works of France, consists in directly carburizing one of the faces of the ingots, at the time of casting, by lining one of the vertical sides of the mould with carburizing substances. The carburizing action is prevented from penetrating too deeply into the inside of the ingot by casting the vertical side opposite to the carburizing side. The case-hardened surface is rather rough, but all irregularities disappear in forging, which may be effected without special precaution, and at a comparatively low temperature, by the press.

R. A. Hadfield has recently made some investigation into the properties of iron and nickel alloys which show that the addition of nickel to iron or steel appears to produce an effect similar to annealing. Chernoff, the Russian scientist, has stated that steel is composed crystals of metallic iron cemented together by carbide of iron. Probably in nickel-iron alloys the intercrystalline spaces are more completely filled, thus increasing the cohesion.

Incline Retarding Conveyor.

Lowering coal from high to lower levels is a problem which in the past has, as a rule, been accomplished by means of a system of tramcars. It therefore makes the accompanying illustration of special interest, as the device shown displaces the old tramcar system and has in its favor special points of advantage. The first cost of a conveyor system is less than a tramcar system; it is simple and requires little power and no expert attendance. In the plant illustrated herewith the coal is discharged over the ordinary tipple at the head into a large feed hopper from which it is fed on to the conveyor. The conveyor in this case is made of one of the Jeffrey special wire ropes with coupling attachments, operating over sheaves at the terminals, while the conveyor is carried in a special V-shaped trough. When the conveyor is loaded its full length, and when the feed is continuous, this conveyor acts as a retarder in keeping the coal from running away from itself. To start the conveyor a small motor is necessary; while, when running full, a brake is used to keep the conveyor in check. By the use of this system the coal is carried to the coal chutes or cars below without any breakage at the rate of from 100 to 140 tons per hour. In the plant illustrated herewith the distance from the upper to the lower level is 500 feet. Formerly tramcars were used, and as this system has proven a practical, as well as a commercial success, it will no doubt find favor with others who are operating under similar conditions. This plant was installed by the Jeffrey Manufacturing Co. for the Logan Consolidated Coal & Coke Co., whose mines are at Matewan, West Virginia.

INCLINE RETARDING CONVEYOR.

Antique Cement Analyzed.

Samples of cement used in the antique water conduits about Ephesus and Smyrna were recently subjected to chemical analysis and the various samples were found to be quite similar in composition. The water works from which the samples of cement were taken were constructed from a period several centuries before Christ to 300 years after. The chief constituent of the samples was carbonate of lime, but mixed with it was from 2% to 8% of organic material. This was ascertained to consist of a mixture of fatty acids. Experiments were made with a cement consisting of burned lime and olive or linseed oil, but it was not found to be permanent. On the other hand, a mixture of two-thirds air-slaked lime and one-third olive oil hardened readily, and possessed great endurance, leading to the belief that this was the composition of the ancient cements which were analyzed.—Railway and Engineering Review.

Cyanide Prior to Amalgamation.

To the Editor:—In various districts there are stamp mills with amalgamation plates and facilities for cyanidation of tailings. A Utah millman—Mr. M. D. Stackpole—suggests the advantage of reversing this process. That is, he would cyanide the ore at about ten-mesh, then run it through Huntington mills and over the amalgam plates afterwards. He claims that to crush and pulverize the ore sufficiently fine for amalgamation usually makes it too fine to leach advantageously. Then rusty particles of coarse gold which do not yield to the cyanide will be left in condition to amalgamate readily.

WASCOTT.

A MODERN COPPER SMELTER (ROUND FORM).

THE COLORADO IRON WORKS CO.,

Established 1860. DENVER, COLO.

MANUFACTURERS OF

Smelting Furnaces and Equipments

For the Treatment of

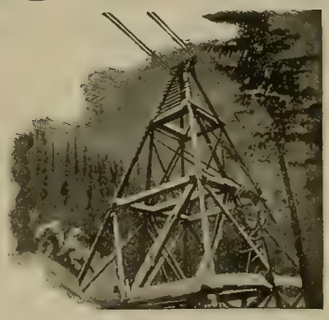
GOLD, SILVER, LEAD, COPPER and PYRITIC ORES.

THIS CLASS OF WORK IS A SPECIALTY WITH US.

We also manufacture all kinds of Ore Milling Equipments for Amalgamation, Concentration, Cyanide and Chlorination Processes.

(SEE PAGE 364.)

THE MINE AND SMELTER SUPPLY CO.,



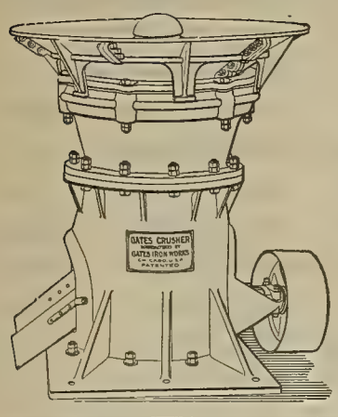
DENVER, - - COLORADO.

Mining and Milling Machinery and Supplies.

We beg to call your attention to

THE FINLAYSON PATENT WIRE ROPE TRAMWAY—

the latest and best system of double-rope automatic aerial tramway in the market.
If interested in the most economical system of transporting ores from mine to mill and to shipping stations, send for our special tramway catalogue.



We carry a complete stock of Machinery and Supplies for immediate delivery.

Send for our special catalogues on Mining Machinery, Milling Machinery, Wilfley Concentrators, Tramways, Power Transmission Machinery, Etc.

THE MINE AND SMELTER SUPPLY CO.,.....Denver, Colorado.
THE MINE AND SMELTER SUPPLY CO.,.....Salt Lake City, Utah.
THE MEXICO MINE AND SMELTER SUPPLY CO.,
No. 16 San Francisco St., City of Mexico.

BOILERS, ENGINES, STEAM HOISTERS, ELECTRIC HOISTERS, ROLLS, CRUSHERS, WILFLEY TABLES, CARS, CAGES, ORE BUCKETS, RAIL, PIPE, FITTINGS, BELTING, ETC., ETC.

GATES IRON WORKS.

The Original GYRATORY BREAKER.

It is ADJUSTABLE, and INDESTRUCTIBLE.

THERE ARE 4,000 OF THEM IN USE.

The South African Mines Have Purchased 200.

. . We build a FINE CRUSHER that is a wonder. . We know how to design this class of machinery. . . . There are others who think they know how to make a Gyratory Crusher; they are simply poor imitators of The Only Great Gates Rock and Ore Breaker. .

Address for Catalogue No. 1, Dept. UU, 650 Elston Ave.. CHICAGO.

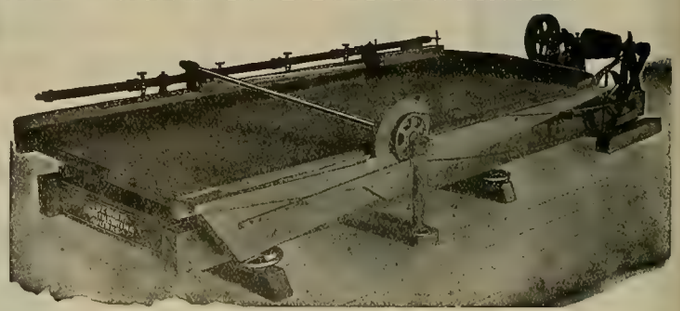
SEATTLE, WASH.

Iron and Brass Founders, Machinists and Blacksmiths.

MANUFACTURERS OF ALL CLASSES OF MACHINERY.

Mining Machinery and Engine Building

A SPECIALTY.



The most modern, completely equipped and up-to-date plant in the Northwest. Everything new from end to end.

THE : CAMMETT : CONCENTRATOR.

Designed with some Regard for the Laws of Concentration.

The perfect vanner motion given to the pulp by our head motion, together with the freedom from "jumping" resulting from the special rigid guides used, explains why the Cammett riffles never "pack," and why the table has such a great capacity when handling slimes. : : : : : : : : : : : : : : : : :

The continuous grooves and riffles extending from end to end of the table maintains the greatest possible margin of safety between the concentrates discharge and the tailings. : : : : :

Thoroughly Protected by Strong Patents. Write for Circular.

30th and Blake Streets, - - - - DENVER, COLORADO.

THE

Pelton Water Wheel Company

Gives exclusive attention to the development and utilization of water powers by the most modern, economic and improved methods. An experience of more than fifteen years, involving both the theory and practice of hydraulic engineering as relates to power development in its widest range of application, is at the service of its customers.

Nine Thousand Wheels Now Running,

Averaging some 700,000 H. P.

ELECTRIC POWER TRANSMISSION.

Pelton wheels afford the most reliable and efficient power for such service and are running the majority of stations of this character in the United States, as well as most foreign countries. Highest efficiency and absolute regulation guaranteed under the most extreme variations of load.

The Pelton Water Wheel Company,

121 & 123 MAIN STREET, SAN FRANCISCO, CAL.

TUTTHILL Patent Water Wheels.

Don't buy any other until you have seen them and investigated their merits. We not only guarantee high efficiency and regulation, but obtain it in actual practice. Estimates and surveys made for the installation of Water Power Plants of all sizes and capacities.

MINE BELL SIGNALS.

Adopted, Used and in Force in Accordance with Law.

We print in legal size, 12x36 inches, the Mine Bell Signals and Rules provided for in the Voorhies Act, passed by the California Legislature. The law is entitled "An Act to Establish a Uniform System of Bell Signals to Be Used in All Mines Operated in the State of California, for the Protection of Miners." We furnish these Signals and Rules, printed on cloth so as to withstand dampness. **50 Cents a Copy.**

MINING AND SCIENTIFIC PRESS. 330 Market St., San Francisco, Cal.

THE MAP SHOWS--

The shaded part shows that where the most metal mining is done the MINING AND SCIENTIFIC PRESS has the largest part of its circulation. It tells its own story. The MINING AND SCIENTIFIC PRESS is the only mining paper that has a general circulation therein. It offers the most economical way to reach the men most likely to be your customers—the men who want to buy what you want to sell.

Nothing is claimed that can not be proved.

Every man who sells what miners buy wants their cash trade. All other advertising mediums combined will not reach so many possible purchasers as this paper alone. In advertising you have the choice of omitting much of this field or using the advertising columns of the MINING AND SCIENTIFIC PRESS.

The region shaded on the map has a **POPULATION OF TEN MILLIONS—MINING IS ITS CHIEF INDUSTRY.**

No advertiser who sells to mining men would omit using this journal if he knew the truth about it. We want to have you know, for if you did know you would put your advertisement in the medium most likely to make your advertisement a profitable investment for you.

Especially, if from any reason you think "Advertising doesn't pay," we would like to furnish you with evidence that the right kind of advertising does pay.

Economy in advertising is like economy in everything else—judicious expenditure of money. The results of an advertisement are what determines its value. : : : :

2949-51 Larimer St. DENVER, COLO.

WOOD'S DEEP WELL PROPELLER PUMP

For Deep or Shallow Lifts.

CAPACITY 100 TO 15,000 GALLONS PER MINUTE.

A simple screw propeller pump without valves or complicated parts. Fits into oil well casing of from 6 to 12 inches diameter and larger, the pump occupying but this space in shafts and in wells without pits dug to water level, and may be operated on an incline or vertically. Specially adapted for sinking purposes pumping out sumps and river bottoms, and for handling large quantities of water economically and successfully. In writing, state work required.

Catalogue and Estimates Cheerfully Furnished.

NO MORE PACKING DIRT TO WATER.
—THE—
PNEUMATIC PROSPECTOR.
Size 6x11x14 in. Weight only 10 lbs.

PACKED FOR MOVING.

NO WATER NEEDED.

Gives a clean prospect from placer ground or free-milling ore by compressed air. The operation is purely mechanical. No chemicals, no quicksilver; no black sand remains with the gold. Will do work equal to careful panning.

THE PNEUMATIC SEPARATOR.
Weight 160 lbs.

Has a capacity of 20 to 30 cu. yds. of gravel per day. Will save fine and coarse gold and nuggets of any size, comparatively free from black sand. Will do better work under favorable circumstances than a sluice box. Indispensable for dry countries.

SEND FOR DESCRIPTIVE CIRCULAR.

WEST BEND, IOWA, U. S. A.

FIRTH'S DRILL STEEL, 16 cents per pound.

The best drill steel on the market. Has no equal for hard rock drilling. Miners cannot afford to use an inferior steel when FIRTH'S can be bought at the above price.

Abner Doble Company, Gen. Agts.,
Fremont and Howard Sts., SAN FRANCISCO, CAL.

—THE—
"Pneumatic" Cyanide Process.

(Patented in United States, South African Republic, New Zealand, Victoria, New South Wales, South Australia; other patents pending.)

Supplies the solution with the oxygen required for perfect extraction. Prevents settling, packing and channelling. Heats the solution and prevents freezing in winter. Doubles the capacity by requiring less than one-half the usual time. Saves the highest percentage of values at the lowest cost per ton. *"Mill rights" sold direct to users; no royalties.*

Send for pamphlet to THE PNEUMATIC CYANIDE PROCESS CO.,

PATENT SOLICITORS,

330 MARKET STREET, - SAN FRANCISCO, CAL.

Inventors on the Pacific Coast will find it greatly to their advantage to consult this old experienced first-class agency. We have able and trustworthy associates and agents in Washington and the capital cities of the principal nations of the world. In connection with our scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of patents already granted, for the purpose of determining the patentability of inventions brought before us, enables us to give advice which will save inventors the expense of applying for patents upon inventions which are not new. Circulars and advice sent free on receipt of postage. Address **DEWEY, STRONG & CO., Patent Agents, 330 Market St., San Francisco, Cal.**

The above illustration shows an operator taking an incline above the horizontal with BRUNTON'S PATENT POCKET MINE TRANSIT. The instrument is made especially for mining engineers, mine managers and superintendents, but its light weight and the ease with which it can be handled render it admirably adapted to the taking of topography and for geological field work. Write for catalogue B, giving full description of the instrument and all its uses, to

No. 043 BUTTON BALANCE, 10-inch beam. Sensitive to 1-100 Milligramme. This is a double-column button balance with all latest improvements, including our new adjusting device and rider rod lock. It is accurate and as rapid as a beam of this length can be. For an office doing a moderate amount of work, it is the best balance to be had for both gold and silver. For complete description and prices of this and other balances send for catalogue A to

THE BRYAN ROLLER QUARTZ MILL.

We are the sole manufacturers of this Mill. A test made by the Bullion-Beck Co. of Eureka, Utah, with this and the Huntington Mill proved conclusively every claim we made for the Bryan Mill, viz: that the Bryan would crush more ore with less repairs, less power and less slimes than any Mill made. Result—they are now operating three of the five-foot Bryan Mills and find them superior and more satisfactory than any Mill they ever used. L. C. Trent & Co., who had formerly sold the Huntington Mill, immediately manufactured a Mill infringing our patent. Suit brought in the U. S. Court resulted in a verdict in our favor, and we shall prosecute to the full extent of the law any infringement of any character whatsoever in the MAKING, USING or SELLING of the same. : : : : : : : : : : :

Strong.

Economical.

Simple.

MANUFACTURED BY

◆◆◆◆◆◆◆◆◆◆◆◆

The BRYAN MILL is constructed on the principle of the Chili Mill, except it has three rollers arranged to run in a continuous discharging pan. It crushes either gold or silver ores. It consists of an annular cast-iron mortar with fixed steel dies arranged in the path of its three crushing rollers. Power is applied direct from a pulley through a bevel gear and pinion secured to stationary center post. We present a few of many advantages it possesses over any other Mill: Larger screen capacity and free discharge. Amalgamates a larger percentage of gold. Quickly and cheaply erected; with regular feed and proper flow of water requires little attention. Crushes hard or soft ore with smaller amount of power per ton and less wear and tear of machinery. : : : :

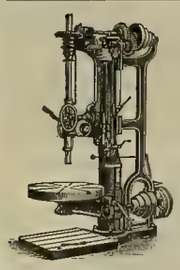
Can I Become An Electric Mining Engineer?

YES, You Can. We guarantee we can make a thorough electric mining engineer of you at your home by our new system of correspondence instruction. Our instruction papers are prepared by the highest authorities and include every branch and method employed successfully to-day in electric mining. Course includes: General conditions of mines; Systems for the application of power; Mine wiring; Signaling; Electric haulage; Hoisting motors; Operation of electric mining installations; Cost of electric mining equipment, etc. Our terms are within reach of all: $5 or $2 per month or cash in advance. *Write for our free illustrated book* (120 pages); it will pay you to read it. We teach also **Electrical and Mechanical Engineering, Mechanical Drawing,** Telegraphy, Telephony, etc., by mail. THE ELECTRICAL ENGINEER INSTITUTE OF CORRESPONDENCE INSTRUCTION, Dept. 21, 120-122 Liberty Street, New York.



I consider the Electrical Engineer Institute as conducted by Messrs Wetzler and Martin to be of great value to those who desire an Electrical education

Market Reports.

SAN FRANCISCO, Sept. 21, 1899.

SILVER. — London, 27⅛d; New York, 58 13-16; San Francisco, 58 13-16; Mexican Dollars, 48@49; New York exchange, sight, 12½; telegraphic, 15 cents premium.

Silver shows a further decline since last week, though only a small fraction; but it is in this manner that the price has steadily declined for several weeks past.

A Washington special says:

It may be an astonishing statement to say the United States Government refuses to accept gold of its own coinage in exchange for silver dollars, but that is what at least one sub-treasurer is actually doing. A complaint comes from St. Louis, where the sub-treasurer declines to exchange silver dollars except for silver certificates. Neither gold nor banknotes will tempt the white coin from his vaults. It is possible for the United States Treasury to reach a point where a general order will be issued to all sub-treasurers forbidding them to exchange silver dollars for gold, national banknotes or any other form of currency except silver certificates.

Uncle Sam presents the remarkable spectacle of trying to get rid of gold and of hoarding silver, all of which is an interesting phase of the wave of prosperity.

While the Treasury has in its vaults gold to the enormous total of $342,691,648, of which $255,022,899 is not covered by gold certificates, and while this dazzling hoard is steadily growing larger, there is a famine of silver dollars. The country is doing such a tremendous business that the people are ravenously hungry for money of small denominations. In the East there is a special demand for $1 and $2 bills. In the West silver dollars have been drawn from the sub-treasuries until their stocks are about exhausted. In all sections there is such a demand for fractional silver that the Government supply will soon be eaten up if the present rate of call keeps up.

The Treasury has on hand $406,576,436 in silver dollars, but most of these must be retained in the vaults for the redemption of silver certificates, which aggregate $406,187,504. This leaves $388,932 in silver dollars in the Treasury and its branches that are not covered by notes.

The Treasury stock of fractional silver is down to $3,456,899, and there is no law for buying any more bullion for this coinage. The Government officials fear the entire stock of small silver will be called into circulation before Congress can take action to meet the great demand.

LEAD.—New York reports quiet, $4.57½ bid, $4.62½ asked; brokers' price, $4.40.

Local, pipe, 7¼@7¾c; sheet, 7¾@8¾c; pig, 6¾c; bar, 6¼c.

COPPER.—New York reports Lake very quiet at $18.50; brokers' price, $18.50. Local —Mill copper plates, 23¾c.

Exports of copper from Japan during the first six months of 1899 amounted to 10,601 tons, against 6268 tons for the same period in 1898. Of the above amounts, 10,270 tons went to Europe in 1899 and 4602 tons to the same continent in 1898. In New York there is a quieter market for copper at 18¾c for the Lake brands, with sellers more numerous at these figures. The market is dull, but prices hold their own. It is not yet known whether the Calumet & Hecla intends to drop its price to 18c on the next sale, but there are some suggestive movements which may or may not be regarded as a forerunner of coming events. There is information to the effect that the stock of Chili bar copper at Liverpool, amounting to between 9000 and 10,000 tons, is to be shipped to this country for treatment in one of the refineries here.

IRON.—American, soft, $22.50@24.50 per ton; Scotch, $27.50 Local bar, 2¾c per lb.

STEEL.—11¼@20c per pound.

TIN.—Weak, $31.75 bid, $32.15 asked; pig, 36@39c per lb.

ANTIMONY.—In San Francisco 1000 pounds and upwards, 10c net; 300 to 500 pounds, 11@14c; less than 100 pounds, 15c.

BABBITT METAL.—No. 3, 8¾c.

QUICKSILVER.—Local, $46; export, $40.50 @41; carload lots, special rates.

The local price of quicksilver has advanced within the past week. The market has shown an upward tendency for some time past.

ALUMINUM.—No. 1, 99% pure in ingots, for remelting, 37c per pound, in small lots; 35c per pound in 100-pound lots; 33c per pound in ton lots and over. No. 2 grade, 90% pure, cast in ingots for remelting, 34c per pound in small lots; 33c per pound in 100-pound lots; 31c per pound in ton lots and over. Aluminum castings, according to number, weight, moldings, etc., 45c per pound, upward. Aluminum sheet from 38c per pound upward. Lots of less than 50 pounds, 5c per pound higher. Nickel aluminum casting metal, 39c per pound in small quantities; 35c in 100-pound lots and 33c in ton lots.

PLATINUM.—London, 68⅔s per ounce; York, $16.25; San Francisco, $16.75.

ASSAY LITHARGE.—100 lbs., 12c.

POWDER.—F. o. b. San Francisco: No. 1. 70% nitro-glycerine, per lb., in carload lots, 15¼c; less than one ton, 17¼c. No. 1*, 60%, carload lots, 13¾c; less than one ton, 15¼c, No. 1** 50%, carload lots, 11¾c; less than one ton, 13¾c. No. 2, 40%, carload lots, 10c; less than one ton, 12c. No. 2* 35%, carload lots, 9¼c; less than one ton, 11¼c. No. 2** 30%, carload lots, 9c; less than one ton, 11c. Black blasting powder in carload lots, minimum car 728 kegs, $1.50 per keg; less car lots, $2 per keg.

FUSE.—Triple tape, $5.10 per 1000 feet; double tape, $4.35; single tape, $3.45; Hemp, $3; Cement No. 2, $4.35; Cement No. 1, $3.45.

CAPS.—3x, $5.50 per 1000; 4x, $6.50; 5x, $8; Lion, $9.

CHEMICALS.—Cyanide of potassium, 98%–99%, jobbing, 32@33c ℔ lb.; carloads, 29@30c; in 10-lb. tins 37c; sulphuric acid, 1¾c per lb. 66° B.; soda ash, $1.60 per 100 lbs. 58%; hyposulphite of soda, 2½@2¾c per lb.; blue vitriol, 5¼ @6c per lb.; borax, concentrated, 7@8c per lb.; chlorate of potash, 12@13c; roll sulphur, 6c; alum, $1.90@2.00; flour sulphur, French, 2¼@ 2½c; California refined, 1¼@1¾c; nitric acid, in carboys 8c per lb; caustic soda, in drums, 3@4c per lb.; Cal. s. soda, bbls., 65c; sks., 60c ℔ 100 lbs; chloride of lime, spot, 2.10@2.25c; nitrate of potash, in kegs, 8c; chlorate of potash, 25c; caustic potash, 10c in 40-lb. tins.

CANDLES.—Electric Light Candles—6s, 16 oz., 8¼c; 6s, 14 oz., 7¾c; 6s, 12 oz., 5½c; 6s, 10 oz., 5½c; Granite (Mining) Candles—6s, 16 oz., 9¼c, 6s, 14 oz., 8¾c; 6s, 12 oz., 7½c; 6s, 10 oz., 6½c. Paraffine Wax Candles—1s, 2s, 4s, 6s, white, 10c; colored, 11c.

OILS.—California Castor, pure, cs., $1.10 per gal.; bbl., $1.05; pure No. 2, cs., 85c; bbl., 80c; Baker's AA Castor Oil, in case lots of 200 gals. and upward, $1.15; less than 200 gals., $1.10; in bbls., 4c per gal. less than case; Baker's Crystal, $1.40; China Nut, 50c; Linseed, strictly pure, boiled, bbl., 50c; cs., 55c; raw, bbl., 48c; cs., 53c; lots of 5 bbls., 1c less; Lucol, boiled, bbl., 44c; cs., 49c; raw, bbl., 42c; cs., 52c; lots of 5 bbls., 1c less. Kerosene—Pearl, cs., per gal., 16½c; Astral, 16½c; Star, 16½c; Eocene, 18¾c; Extra Star, 20½c; Elaine, 21½c; Water White, bulk, in tanks, 11¾c; Mineral Seal, iron bbls., 21c; wooden bbls., 23¾c; cs., 26c; Mineral Sperm, 27c; Deodorized Stove Gasoline, bulk, 16c; do., cs., 21c; 86 deg. Assessment Notices.

CALIFORNIA BORAX COMPANY. — Location of principal place of business, San Francisco, California. Location of works, San Bernardino County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 13th day of September, 1899, an assessment (No. 1) of Two ($2) Dollars per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the secretary, at the office of the company, No. 310 Pine street, rooms 15 and 17, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 30th day of October, 1899, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on TUESDAY, the 28th day of November, 1899, to pay the delinquent assessment, together with the costs of advertising and expenses of sale.

By order of the Board of Directors.

J. W. PEW, Secretary.

Office—No. 310 Pine street, rooms 15 and 17, San Francisco, California.

MARINA MARSICANO GOLD MINING COMPANY. — Location of principal place of business, San Francisco, California; location of works, Sunny Hill, Shasta County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 16th day of September, 1899, an assessment (No. 20) of 5 cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin to the secretary, at the office of the company, 217 Sacramento street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 24th day of October, 1899, will be delinquent and advertised for sale at public auction; and unless payment is made before, will be sold on WEDNESDAY, the 15th day of November, 1899, to pay the delinquent assessment, together with the costs of advertising and expenses of sale.

By order of the Board of Directors.

CHARLES BOVONE, Secretary.

Office—217 Sacramento street, San Francisco, California.

KATE HAYES MINING COMPANY.—Location of principal place of business, San Francisco, California; location of works, North San Juan, Nevada County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 24th day of August, 1899, an assessment (No. 7) of One Dollar per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the secretary, at the office of the company, 320 Sansome street, room 24, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 26th day of September, 1899, will be delinquent and advertised for sale at public auction; and, unless payment is made before, will be sold on WEDNESDAY, the 18th day of October, 1899, to pay the delinquent assessment, together with the costs of advertising and expenses of sale.

By order of the Board of Directors.

JOSEPH H. MOOSER, Secretary

Office—320 Sansome street, room 24, San Francisco, California.

BADGER HILL AND CHEROKEE GRAVEL MINing Company.—Location of principal place of business, San Francisco, California; location of works, Cherokee, Nevada County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 24th day of August, 1899, an assessment of Three Dollars per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the secretary, at the office of the company, 320 Sansome street, room 24, San Francisco, California.

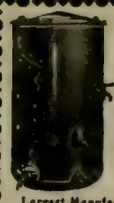
Any stock upon which this assessment shall remain unpaid on the 27th day of September, 1899, will be delinquent and advertised for sale at public auction; and, unless payment is made before, will be sold on THURSDAY, the 19th day of October, 1899, to pay the delinquent assessment, together with the costs of advertising and expenses of sale.

By order of the Board of Directors.

JOSEPH H. MOOSER, Secretary.

Office—320 Sansome street, room 24, San Francisco, California.

CONSOLIDATED CALIFORNIA & VIRGINIA Mining Company.—Location of principal place of business, San Francisco, California; location of works, Virginia Mining District, Storey County, Nevada.



Notice is hereby given, that at a meeting of the Board of Directors, held on the 6th day of September, 1899, an assessment (No. 14) of 25 cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the secretary, at the office of the company, room 29, Nevada Block, No. 309 Montgomery street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 11th day of October, 1899, will be delinquent and advertised for sale at public auction; and unless payment is made before, will be sold on WEDNESDAY, the 1st day of November, 1899, to pay the delinquent assessment, together with the costs of advertising and expenses of sale.

By order of the Board of Directors.

For Testing Placer Ground.

Sinks and drives 6, 8 or 10-inch pipe through boulders; takes all the loose material out, including gold, as the hole is sunk. Does the work at a very small cost. Drills water and oil wells and mineral test wells through any kind of rock to 1500 feet. Several sizes. Unexcelled for lead and zinc testing.

KEYSTONE DRILLER CO., Beaver Falls, Pa.

FOUR and SIX-FOOT FRUE VANNERS

With Brownell "Patent Lip" Flange Belts.

STANDARD MACHINE OF THE WORLD.

When a Concentrator like the Frue Vanner has been on the market nearly two decades, and the sales have constantly increased, it is safe to say it is the "Standard Machine of the World." More Frue Vanners have been sold during the last twelve months than for the same period at any time during the history of the machine. Practical mining men in all parts of the world where mining is carried on will testify as to its merits. It is the "standard" which all competitors are trying to imitate.

The results obtained by this machine are the "acme" of concentration, and several cheap and untried machines that have lately come on the market compare by it. The manufacturers will tell you that they are "just as good, and cheaper," etc. The facts are that no other concentrator made has an equal capacity, or will yield as clean a concentrate with as small loss in the tailings as the Frue Vanner. The amount saved from the lower first cost of an inferior machine counts little in the year's results, when compared with the increased output from a Frue. This machine not only gives better results at both ends of the belt (i. e., clean product and poor tailings), but is operated at less expense and requires less attention than any other machine on the market. At the Alaska-Treadwell mine, where they have ordered over 350 Frue Vanners, one man attends 48 machines for 12-hour shift.

MANUFACTURERS OF

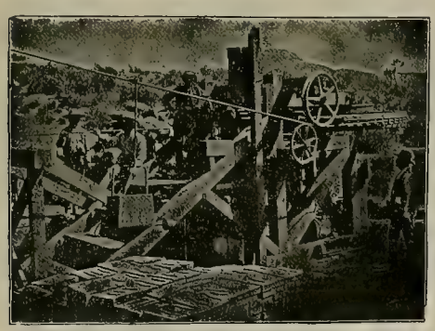
Gold Dredging Machinery

And COMPLETE EQUIPMENT for Placer Mines

OUR SPECIALTY.

We build **GOLD DREDGES COMPLETE IN RUNNING ORDER** to handle 2500 cubic yards per day at a cost of 3 cents per cubic yard.

We excavate 50 feet below water, 20 feet above water and handle boulders up to one ton weight.



Send for Dredging Catalogues Nos. 15 and 16.

WE ALSO BUILD

All kinds of Mining, Milling, Concentrating, Pumping, Air Compressing, Hydraulic, Water Wheel and Hoisting Machinery.

EVANS HYDRAULIC GRAVEL ELEVATORS.

We publish sixteen catalogues. Write for one in the line you are interested in.

THE HALLIDIE ROPEWAY

For transporting Ore, Fuel, Merchandise, etc., in bulk or in packages.

SIMPLE, ECONOMICAL, INEXPENSIVE, PRACTICAL.

LOADS MECHANICALLY. DUMPS AUTOMATICALLY. Send for Ropeway Pamphlet No. 20.

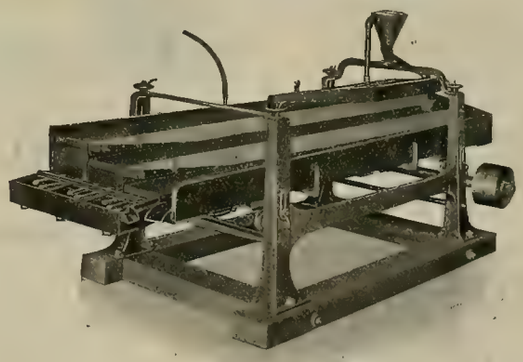
Cableways, Double Rope Tramways, Wire Rope Transmissions, Incline Planes, Logging Machinery, Suspension Bridges,

DESIGNED, FURNISHED, ERECTED. Write for Estimates.

CALIFORNIA WIRE WORKS, - 9 Fremont St., San Francisco, Cal.

THE BARTLETT CONCENTRATING TABLE.

One of these Machines will take the place of TWO or THREE Belt Concentrators of any make and do as good work.



Separates ALL the minerals from each other at one operation.
Gives THREE CONCENTRATES on the one Machine at the same operation.
The Machine is especially adapted to the separation of Zinc and Lead.

- PRICE: -

12-ft. Table, $350.

SHIPPING WEIGHT - - - - - 2200 POUNDS.

CAPACITY - - - 10 to 30 tons per 24 hours.

Parties desiring tests made can send 500 lbs. or more, charges prepaid, and a run will be made and reports forwarded of the results, free of all charges, except for the assays, which will not exceed $10.00.

CAN BE SET UP ANYWHERE.

REQUIRES NO SPECIAL FOUNDATION.

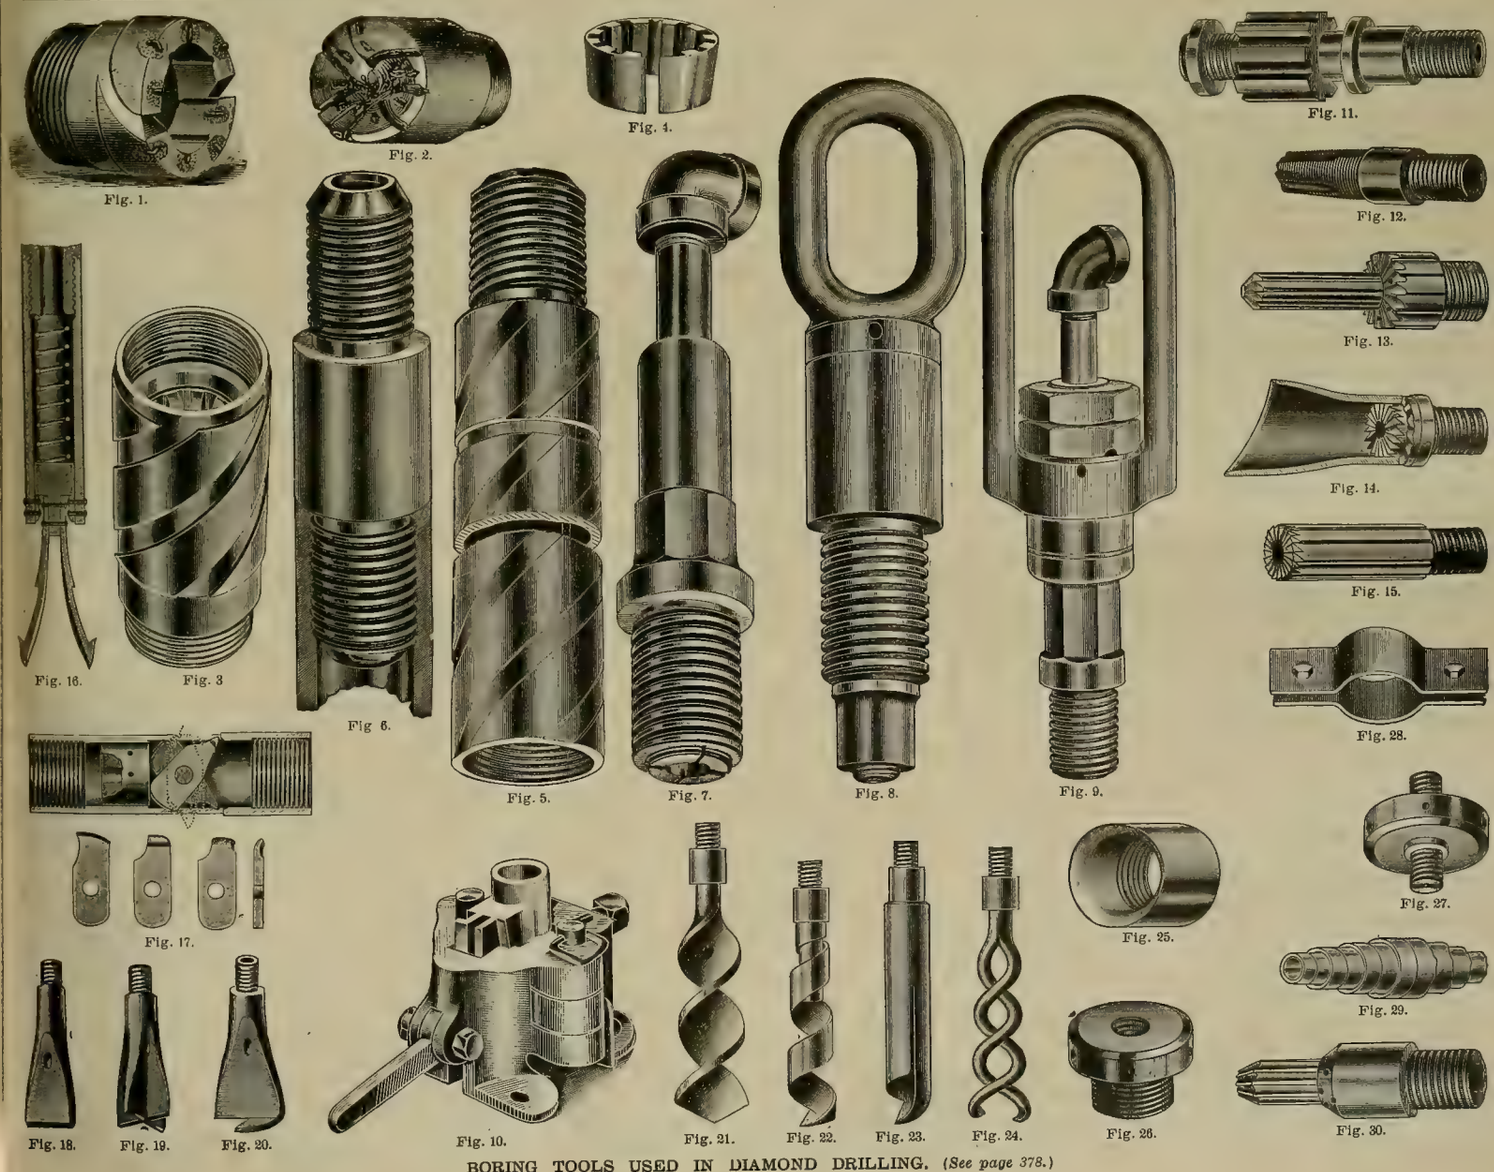
The Vagaries of Geology.



It is not strange that geologists do not always agree upon the origin of geological occurences which are not absolutely plain to all. No geologist, having seen it, will dispute that the Grand Canyon of the Colorado river, in Arizona, has been formed by the erosive effect of the river and its sediment, scouring throughout a long period while the land was slowly rising. There are, however, other geological features less profound but far more difficult of interpretation. The correlation of geological formations far removed from each other is one of the most difficult problems with which the geologist has to deal, particularly in the case of azoic rocks which, containing no fossils, leaves their determination to lithological features only, and consequently geologists do not always agree as to the age of this formation or that.

An overturned fold often results in a perplexing problem where the exposures are poor, occurring only in patches, and when the result is observed—that of an older formation lying upon a younger—there appears room for discussion as to the existing conditions. The age of certain uplifts has been the cause of much discussion, and in the determination of the facts geologists are not always of one mind. To one the evidence may indicate that the occurrence took place during cretaceous time, and another will find what he considers sufficient evidence to justify the belief that it did not occur until the tertiary period.

Often when a mining geologist goes to examine a mine for the first time he forms impressions which seem well founded, but a subsequent observation and more careful study satisfies him that his first impression was incorrect. Had he not gone back and taken a more careful look he would have left the place satisfied as to the character of the occurrences, and another coming later, discovering the true conditions, a disagreement would arise. All are liable to error, and one should not condemn too hastily the opinion of another without first investigating from the standpoint of view of the other.

It is an uncommon thing to find carboniferous limestones and schists lying upon quarternary gravels, yet such an occurrence exists in California, in the Black Hawk mountains of San Bernardino county. It is the result of a thrust fault, but it should be seen to be understood. Faults are important factors in the earth sculpture in some regions, and the fact that the puzzling conditions observed are not readily understood suggests the necessity for study in that direction.

The practical miner gives most of his thought and attention to the conditions he finds from day to day in his shaft or in the face of his drift, giving little thought to the broader questions involving the origin of his vein and its relation to its surroundings. He exposes the evidence of nature's work foot by foot and has the best opportunity for observation, but destroys the evidence as he goes, and too often pays little heed to it.

SINCE the smelters have resumed operations in Colorado the works are surfeited with ore. One of them has nearly 20,000 tons stacked up, and the supply continues unabated.

AN Eastern financial journal, describing a gold property in Tuolumne county, California, says: "The Harvard has a quarry nearly 500 feet high, 4000 feet long and between 600 and 700 feet wide, which runs about $4 per ton in free milling gold." This constitutes a mass of ore containing 100,000,000 tons, worth nominally $400,000,000. A very good property to own, as with a mill of 1000 stamps crushing 4000 tons daily it would last seventy years, and then only be worked down to the bed of the river. But this magnificent mine is eclipsed by the statement coming from Santa Fe, New Mexico, where it is claimed there are $800,000,000 of gold in sight in the magnetic iron mines. Fortunately these statements are so grossly exaggerated that no one believes them, and consequently they do comparatively little harm. If either of these stories be discounted to the one hundred thousandth part it would still leave a greatly exaggerated statement which facts could not sustain. What useful purpose such reports are supposed to subserve is not apparent.

Rights of Property Holders Along a Stream.

The rights of property holders along the bank of a river has recently come into question again near Oroville, in Butte county, Cal., by a number of persons taking up land on Feather river between the lines of the owners' lots and the stream itself, it has been stated, for the purpose of dredging for gold. It has been formerly maintained that the rights of property holders located along streams extended to the center of the stream, but recently it has been asserted that the rights only extend to the meander lines as indicated by the United States Geological Survey.

The proper solution of this question will depend somewhat on the nature of the original grant and the intent of the grantor in making the conveyance. As a rule the meander lines are run on lakes and streams, not for the purpose of establishing a boundary for the land, but in order to determine the quantity of upland to be paid for by the purchaser.

Ordinarily, a meander line is not a boundary, but water whose body is meandered is the true boundary, whether it in fact coincides with the meander line or not. The owner of the lands so bounded has a right to follow the water as it recedes, and he is entitled to all lands which may be added by recession or accretion. On navigable streams the boundary is low water mark; on non-navigable, the center or thread of the stream.

As a general rule, we do not think land lying between a government meander line and the actual water boundary can be located under the mining laws after the government has issued its patent for the land bounded by the meander line.

Let There Be Light.

In his official address at the opening of the session of the American Institute of Mining Engineers in San Francisco on the 25th inst., President James Douglas among other practical points brought out clearly the good sense in every way of mining men, letting each other and the world in general know what they were doing. His remarks on that occasion will be found on page 373 of this issue. They deserve the favorable consideration of miners everywhere. They supplement and endorse what this paper has so long maintained, viz: the desirability from every point of view of publishing to the mining world the result of practical mining work. The time has gone by when there were great trade "secrets" in mining or anything else. There is a general consciousness of this, an increase of fraternity, a willingness to profit by others' experience, and to share in the dissemination of knowledge that is in happy contrast to the old hide-bound style of suppressing technical information, and it is with pleasure this paper notes so powerful an ally as the president of the greatest technical society in the world.

Some time ago in these columns this subject was given considerable space. Some of what was there said is here reproduced, it being necessary to quote what could not at present be improved:

In its many years of continuous and successful existence this paper has made the interchange of ideas and personal experience one of its strongest features, thus constituting it a medium of communication between progressive men, mutually aiding each other. Such contributions are always welcome, and those who feel so disposed are hereby requested to note the value to themselves of such articles and in their own case to make such contribution as they feel their knowledge or experience justifies. No one is asked to send all he knows, but many of our readers know a good deal about some one thing connected with progressive mining and on that particular thing each is here individually asked to send a few practical points that will doubtless be of considerable value to others elsewhere who are in doubt on the very matter that he has successfully solved. Everybody is wiser than anybody, and in a technical paper like this much of its practical value is due to articles written by men who have in their own experience proved that what they are writing about is an accomplished fact.

The suggested description or discussion can be as long or as short as its writer may deem necessary. Sometimes 100 words will tell all that is needful; in other cases 2000 may he needed to properly explain the matter under discussion. Sketches, photographs, and, in fact, all manner of illustrations can be used (except "blue prints"), the engravings made therefrom embellishing and adding to the value of the communication.

Quite often the impulse exists, but a man is too busy or too tired. Yet nearly every intelligent miner has some time in his life done something in his line that he is proud of, or that he thinks or feels is about as good as any one else could have done under the circumstances; something hard, or unusual, that took all his wits to make a success, or at least not a failure. There are a thousand things in mining that deserve the notice and world-wide publicity accorded by publication in this paper, and any one, anywhere, who reads this will please consider it a special invitation to him to write down some past or present experience of his and send it to us. Here are over a hundred suggestive topics that occur to the mind of the writer during the time devoted to the writing of this article:

How to best save the fine gold when milling cemented gravel in drift mines; an example of successful co-operative mining; profitable working of a custom stamp mill; the building and operation of a wing dam; best arrangement for drop of stamps and why; experience with hydraulic elevators; improvement in arrangement of pipe lines and delivery of water through monitors; daily work of a small cyanide plant; leaching carbonate copper ore with sulphuric acid; results of this season's river mining; cost of mining and milling gold ore; practical method of mine examination; economical work in running a tunnel in hard ground; treatment of low-grade copper ore; relative value of electric and compressed air power, by one who has tried both; how a fire in a shaft was successfully handled; sampling lead ores; retorting amalgam; main requisites in a mining report; improvements in gold milling; use of liquid chlorine in chlorination process; proper contour of silver-lead furnaces; example of profitable treatment of mine tailings; how a leaser made his lease profitable; new points in mine timbering; successfully resisting a "claim jumper"; best location and arrangement for a good mill; experiences of a prospector; overcoming of machinery transportation difficulties; system of fire protection in a mining camp; building a pipe line; satisfactory instance of profit sharing"; wear and tear of shoes and dies; best disposition of smelter slag; record of unwatering a mine; building and maintaining reservoir dams; successful record of a California debris storage dam; timbering in drift mines; utilization of waste water; admission of visitors into a mine; relative value of zinc dust and zinc shavings in cyanide process; amalgamation tests; relief in case of mine accident resulting in personal injury; best arrangement of 10 stamp mill; successful securing of gold from black sands; to obviate loss in scorification assays; use of chuck-block in mortar; working with an arrastra; assaying concentrated sulphurets; slow vs. rapid-drop stamps, prospectors' drill; cam improvements; belting on concentrators, incline vs. vertical shafts; river dredging; mining low-grade cinnabar ore; ditch and flume building; wooden vs. iron battery frames; lead dust accumulator; rawhiding ore; flashlight photography; practical working of miners' unions; battery sizing boxes; sharpening drills; effective form of rolls; making valuable an abandoned mine; what a dry washer can do; proper duties of a mine foreman; removal of amalgam from copper plates; economic matting of sulphide ores; ore sampling in mill; organizing a joint stock mining company; one day in a mine manager's active duties; development of a "prospect" into a paying mine; successful drainage of a deep shaft; ventilating a drift mine; best weight for stamps; suitable arrangement of mill building on site; putting off large quantity of blasting powder; vertical vs. horizontal engine for stationary work; how "assessment work" is done; experience with iron riffles as a gold saver; timbering an incline shaft; changes in stamp practice; developing a prospect; selling a mine; operation of an amalgamator; details of cost of 6x8 tunnel; some ultimately successful mistakes; transmission of power; oil as fuel; spontaneous combustion; ore sorting; mine inspection; application of belts and pulleys; utilization of water power; cleaning up after a cave; good method of bank blasting; concentrator work; improvements in sluice building; ore amalgamation in the mortar; chlorination tailings as flux in smelting galena; best ore crushing for cyanide process; errors in mill construction, etc.

The above proposed topics are merely suggestive; as many more, probably better and equally practical, will readily occur to many of our readers, the idea being to illustrate the manner of mining work that could with common profit to the mining world be presented in this open forum. "My light is none the less for having lighted that of my neighbor," and in all ages the passing on of a light has symbolized the increase of knowledge in all the useful arts and sciences. Science is organized knowledge; art, its application; and in all the wide domain of arts and sciences none is more generally useful than the art and science of mining; no men are better fitted to give instruction therein than those who have successfully solved so many of its problems and worked them out in practical detail. It is from this class of men, scattered throughout this west half of America, that this journal cordially invites such communications, that their work may receive permanent record herein and be of value to so many others also at work in the development of this nation's great basic industry.

Concentrates.

TOUGH ROCK requires wider holes than brittle rock.

MURIATE (chloride) of copper is green—darker than malachite.

FOR fuel purposes three barrels California oil are considered equivalent to one ton of ordinary coal.

THERE are 3000 shareholders in the Calumet & Hecla Copper Co., very few of them hold over 1000 shares.

THERE are no zinc reduction works on the Pacific Coast. The Chapman Co., 422 Battery St., San Francisco, buy antimony ore.

IN the last fifty years the State of California has yielded an aggregate value of eighteen hundred million dollars in mineral products.

IN a placer location of 160 acres by an association but one discovery is sufficient. Such association must consist of at least eight individuals.

ALTHOUGH liquid air is reported to have been successfully used in blasting operations, it has not as yet come into extended use, nor is it likely to.

IT is stated that on a clear day the summit of the mountain Fernando Po, off the west coast of Africa, can be seen at sea from a distance of 250 miles.

THE original gold nugget found by Marshall at Coloma, Cal., Jan. 19th, '48, is now in the possession of W. W. Allen, 323 Phelan building, San Francisco.

A DESIDERATUM is a blasting powder, safe to handle and equal to the various grades of nitro powder, which, upon exploding, shall make no noxious gases.

THE new Tamarack shaft, near Houghton, Mich., will be completed in two years more. It has five compartments and connects with levels two miles in length.

NATIVE TELLURIUM is rare, but is found in Boulder county and in other parts of Colorado. It is most commonly granular, massive, but sometimes occurs in six-sided prisms.

AT one period in its history the Robert E. Lee mine on Fryer Hill, Leadville, Colo., produced about $117,000 in seventeen hours. The ore was very rich in chloride of silver.

COLORADO mine owners have now to advertise for working miners, and the usual line in the morning papers, warning miners looking for work, to "keep away," is absent.

MINERS who have been making new locations for Uncle Sam are returning from the extreme east or west, where they have aided in perfecting title and doing location work.

Most of the ore deposits of Cripple Creek, Colo., occur in andesite breccia, but the veins also extend downward into the underlying granite. The Independence mine is in granite.

QUICKSILVER MINES, like those of copper, gold and other metals, can be made profitable on a very low percentage of metal if the deposit be large and other conditions are favorable.

THE ridiculous statements about molybdenite are not to be believed. Molybdenite is not used on this coast. Concentrated to a product of high percentage, it is worth about $200 per ton.

A GASOLINE engine uses about .12 gallon of gasoline per brake H. P. hour. Gasoline is rated according to its specific gravity, 74° Baume gasoline is ordinarily used, 72° and 76° being also employed.

FLUORITE, or fluor spar, treated with sulphuric acid, evolves an acid which will etch glass. Hydro-fluoric acid cannot be kept in glass bottles for this reason. It is put in leaden or rubber bottles.

THE treatment of ore in every mine is at first largely a matter of experiment, and it would be true economy at the start to employ a competent man to give the necessary information connected therewith.

MACHINE drills are simple in construction and are self operating with either steam or air, but there are many things concerning machine drills and their operation which can not be learned in a day as some suppose.

THE eucalyptus (red and blue gum) of Australia makes superior mine timbers when round, but are not as good as pine when squared, owing to variations in the grain. This timber is used extensively in Australian mines.

IN some ores the gold occurs in association with other minerals which render amalgamation difficult or impossible. The gold may in some cases be obtained by concentration, where amalgamation or other methods fail.

To determine the h. p. of a water supply, multiply number of gallons flow per minute by pressure in pounds per sq. in.; divide product by 1500. To find "pressure in pounds per sq. in." multiply number of feet fall by 0.433.

THE two samples of mica from Independence, Cal., and Shasta, Cal., are not large sheets enough to be of commercial value. The value of mica is in direct proportion to the size of the sheet and the ability to cleave it economically. Good sheets 10x12 inches ought to bring $10 per pound.

AN "original locator" can locate as many more claims as he wants to, and by doing the required amount of assessment work, can hold them. A woman or a minor can locate, and, by complying with legal requirements, can hold a mining claim.

SOME big "dumps" in California, containing many thousand tons of tailings suitable for cyaniding, are at the Utica mine, Angels; Zeila and Kennedy mines, Jackson; Voorhies & Barney, Sutter Creek and Drytown; Golden Gate Mining Co., Sonora; Alvinza Hayward, Plymouth. There are countless other lots of smaller quantity.

THE so-called "clay" often found as an accompaniment of mineral veins in some instances is not clay at all, and contains merely a trace of aluminum, being, in fact, silica in an extremely fine state of division, yet possessing some of the physical properties of clay.

A MINE MANAGER recently testified that a property which had been under his management for four years never paid more than expenses. On being questioned more closely he said the mine paid no profits, but the dividends came from the boarding house and store.

SPOKANE, WASH., wants to build a smelter, and wisely debates its site, whether to erect it where the prevailing winds will blow the fumes through the town, or build outside and with a view to subsequent sanitary requirements.

SCHEELITE, containing 67% of tungstic acid, has been worked at Macraes, Otago, New Zealand. It is found associated with the ore—an auriferous lode—and is obtained by crushing the quartz, the scheelite being recovered by concentration.

"CHEAP" ASSAYING is like "cheap" advertising. In both cases it is not what you pay, but what you get for what you pay that determines the value. "Cheapness" is only a relative term, and "cheap" work is very often the costliest kind to those who pay for it.

WHERE several holes, heavily charged with nitro powder, are to be fired in a shaft, in which it has been necessary to carry the timbers near to the bottom, it is not advisable to discharge them simultaneously by means of the electric spark, as great damage to the timbers may thus result.

SOFT GROUND may be blasted with black powder to better advantage than with nitro powder. Hard ground requires high-grade (No. 1) powder; medium ground, No. 2. When breaking short ground deep holes are not advisable, except where the previous blasts have left a particularly favorable condition.

NITRO POWDER freezes at about 42° F. There is great danger in thawing powder when once frozen. It should be handled as little as possible. It may be safely thawed by placing in a tin can or bucket, surrounded by warm water, which is very gradually heated. Nitro powder must not be subjected to sudden changes of temperature.

THERE are numerous shafts in California drift gravel mines more than 500 feet in depth, in most instances the upper portions of these holes being in the volcanic or lava cap covering the gravel. There are also gravel deposits through which no shafts have been sunk, exposed in old hydraulic workings, 600 feet below the original surface.

NEAR Stockton Hill, Arizona, is found a vein carrying a complex ore, in which iron, lead, zinc and copper sulphides are prominent, with usually good values in silver and low values in gold. Crossing this vein at a right angle is another vein composed almost wholly of quartz, but carrying a small amount of iron and copper sulphides and rich in gold.

WHERE there is a soft streak in a vein or where the vein itself is soft, it is usually good practice to pick out the soft material before blasting, as better headway may be made by so doing. It is not advisable to attempt to pick out the soft material further than can be conveniently done, as the loss of time would soon overbalance any gain otherwise obtained.

WHERE the low grade of the ore does not permit an extensive system of timbering and filling, the vein is worked in a series of large-sized rooms or stopes, timbered sufficiently to keep up the ground temporarily, and the pillars removed later, the ground being allowed to cave. This system is employed extensively in the Lake Superior region and the mines are worked very cheaply.

WHERE a shaft passes through the loose, soft earth or decomposed rock near the surface, which when dry stands well enough, close lagging should be done, for ground of this character when wet often runs badly and may later cause much trouble. As depth is attained and the ground becomes more firm the lagging may be spaced, and still deeper, where it is hard, lagging may often be dispensed with.

MOLYBDENITE and molybdate of lead are not the same mineral. The former is a soft, metallic, scaly, foliated mineral of glossy lead color, and is the sulphide of molybdenum. Molybdate of lead is a soft, brittle mineral, of light yellow to red color, having no metallic luster. It sometimes occurs with other lead ores and is not a desirable mineral in any large quantity, either in the mill or smelter.

"I am often too busy to read your paper through," writes a Sacramento, Cal., subscriber, "but I always read the advertisements. Without derogating from the value of the reading articles and items, I think the advertisements are very interesting. Recently I wanted to buy about $400 worth of machinery and upon looking through your paper found advertised just what I wanted."

THE American Consul at Pretoria calls the attention of the State Department to the fact that under the laws of the Transvaal Republic all residents may be impressed into military service, regardless of nationality, and urges that strong representations be made to the Boer Government before the outbreak of hostilities, in order to prevent the impressment of 1000 Americans in that country liable to military duty.

A SAW OUT may be made at the center of the inner side of wall plates used in shafts, for the purpose of lining up the sets, but it is unsafe to depend upon this center cut alone, for while the center lines may coincide exactly the ends may swing either in or out of a true line and result in a very bad job. The only safe way is to hang a plumb line at each corner, and line up three, four or even more sets at one time, then if they are "true" at the corners the centers must be in line.

APATITE is calcium phosphate. It occurs in crystalline rocks and granular limestone. In size the crystals range from extremely small, microscopic, needle-like objects found in various feldspars and other minerals as inclusions to large masses. In Ottawa, Canada, the Archæan formation contains large amounts of calcium phosphate. Some of the crystals are 1 to 2 feet in diameter and weigh hundreds of pounds. Large green apatites are also found in the granites of the Harney peak range, South Dakota.

TUNGSTITE is a yellow powder or incrustation occurring with wolfram, and is a result of its decomposition. Besides wolfram, the tungstate of iron and manganese, there are manganese tungstate (hubnerite), an iron tungstate (ferberite), lead tungstate (stolzite), which occurs in square octahedrons or prisms, and in color is green, gray, blue or red and has a resinous luster. Calcium tungstate is scheelite. It is usually found massive; in color, white, pale yellowish, brownish, greenish or reddish. It is transparent to translucent.

THE drying of ores by calcining previous to dry crushing often does more harm than good, particularly where the ores contain much sulphide mineral, as the partial oxidation of the sulphides interferes with the perfect operation of the cyanide process. The ores should either be dried by a long-continued low heat, or be thoroughly roasted, burning or volatilizing all of the sulphur present. Complete roasting can not be accomplished by the continuous kiln process, which requires the ore to be treated in large lumps, for the reason that the heat is insufficient to thoroughly oxidize the interior of these lumps of ore.

REPLYING to Kingman, Arizona: The territorial law of Arizona requires that all locations and registrations of mines and mineral deposits made in any of the mining districts of the Territory shall be filed with the County Recorder for record within sixty days after the same shall have been located. The law has been interpreted to exclude the first day—the day of location—and include the last day. Thus a claim located at any hour on January 1st after midnight December 31st would count January 2nd as the first day, January 3rd as the second day, etc. The sixty days would therefore expire March 2nd at midnight, in any year excepting leap year.

THE recent statement herein that in California all corporation stock of a Cal. corporation is assessable was correct and unassailable. The latest decision to that effect was in the Los Angeles, Cal. Superior Court, in July, '98, where in a contested case the judge closed his decision thus: "No power existed in the corporation to waive the legal right as to assessment on account of debts, or that the contract that no assessment would be made applied only to the unpaid subscription price. Accepting either theory, the stock issued to defendant remained assessable for the purposes for which this assessment was levied, notwithstanding the endorsement upon the certificates."

IN sinking a shaft on a small vein in granite, the vein dipped out of the shaft; but, it being desirable to continue the shaft vertically, this was done; as the vein in its dip got several feet from the shaft the granite became extremely hard. A crosscut was run, showing the vein to be about 5 feet from the shaft and approximately parallel with it, standing vertically. It was then determined to enlarge the shaft by cutting out to the vein. The result was a saving of 30% on the cost per foot in sinking during the first week and more than 50% during the succeeding weeks. The vein eventually dipped back into the shaft. This shows that it is often less expensive to remove all of the ground to a good breaking crevice, as a gouge, vein or fissure, as it facilitates breaking the ground.

A TUNNEL driven at the Red Point mine, on the Forest Hill divide, in Placer Co., Cal., was run several hundred feet before striking the channel. When the channel was worked it was eventually learned that the channel might have been reached within a few feet of the mouth of the tunnel; but the fact was not previously apparent, owing to the surface debris. At the Gray Eagle mine, on the same ridge, a shaft was sunk several hundred feet to prospect for a channel, and gravel was found, apparently in the channel. A tunnel was run several thousand feet to tap the bottom of the shaft, when, upon reaching it, the discovery was made that the shaft had struck a depression on the rim, and the tunnel had to be turned up-stream and run several thousand feet before bedrock was reached, on the main channel; which illustrates how difficult it is to see into the ground.

In the issue of the 9th inst. appeared the following: "'49, California; '59, Pike's Peak; '69, White Pine; '79, Leadville; '89, Cripple Creek; '99,——?" During the three weeks since it appeared have been received numerous letters, each filling in the blank with the name of locality from which the letter came; in several papers have also appeared notices of the same nature. The unanimity with which mining men and mining journals deem their respective localities fitted to fill the suggested requirements speaks well for the activity and promise of all, and is further suggestive of the fact that in many localities now exist conditions relatively justifying attention. In '99, so much is being done in mining that it would be an extraordinary development that would occasion a "rush" or such consequent excitement as occurred in the years of the notable "9s."

Smelters everywhere do business with a view to mutual profit; as do shippers. Whether it be a San Francisco or Utah or Colorado smelting company the ore will find its way to the one where, freight rates considered, the best returns can be had. Thus are found Utah ores going to California and California ores going to Utah. Smelters must have certain ores, and such ore is worth more to them—and consequently more to the shipper—than another kind of ore would be to that particular smelter. For instance, the ore cited from Inyo Co., Cal., sent to the Selby Smelting & Lead Co. of San Francisco may have contained flux, of which they had an excess, and, therefore, they could not work it for less than the stated charge, while a Colorado smelter might be urgently in need of such ore, and consequently make a very low rate of treatment. It must be plain, however, to all that no smelter can work ore for nothing and make a profit; and when this is done it is because their need of certain kinds of ore compels them to do so.

THE fissure veins of California are usually, though not always, accompanied by dyke rocks. The most prominent mines in the black slates have dykes as an accompaniment. Among the mines of this type are the Princeton, Hite's Cove, Marble Spring, Red Cloud and Martin & Walling in Mariposa county, where the dykes are fine-grained light-colored rocks resembling felsite. The Sheep Ranch mine, in Calaveras county, is in black slate and has as an accompaniment a granite dyke. The large ore bodies of the Golden Cross mines, at Hedges, in San Diego county, are intruded by irregular masses of pegmatite granite. The Stonewall vein in San Diego county has a granite dyke. The mines of Salt Spring valley all are accompanied by diabase dykes. In the central gold belt most of the mines are at the contact of altered diabase and black slate, but the Eureka at Sutter Creek and the Plymouth Consolidated mines at Plymouth were associated with dykes. The Bonanza pocket mine occurs within a dyke of diabase. A dyke as an accompaniment to a vein cannot be considered as indicative of value but is evidence of the deep-seated origin of the fissure.

American Institute Mining Engineers.

The twenty-ninth year of existence of the American Institute of Mining Engineers was signalized by the holding of its meeting in San Francisco, California, during the past week. In the early months of the year every detail was arranged by correspondence and wire, so that the local committees in charge were able to carry out the extensive programme. The Institute is world-wide in its membership and influence. There are about 2600 men who constitute this great technical society, and they are found in every part of the earth.

Following is a corrected list to date of their names and residences :

ALABAMA.

Aldrich, Aldrich, W. F. *Anniston*, Noble, A. E. *Birmingham*, Aldrich, T. H., Aldrich, T. H., Jr., Bowron, C. E., Boron, J., Hillman, McCormack, Montgomery, J. It will be noticed that the above list constitutes a roll-call of the most prominent mining engineers and metallurgists, etc., and that it is a Cosmos or World's club. Were half of them to be assembled in one place at one time they would make a large gathering. But it is rarely possible to get more than one-tenth of the members together, for they are largely captains of great industries, or traveling in the employ of themselves or some others on business, so that it was not expected that the delegation coming eastward to join in the session at San Francisco would be a large one.

The local committee in charge left San Francisco on the 23rd inst, twenty-one in number, and met the visiting delegates who had been journeying westward by easy stages from New York City in a special train of private cars since the 15th inst. On the 16th they were 1000 miles on their journey, and left Chicago for St. Paul, Minn.; on the 18th they were at Great Falls, Montana, on the 19th at Butte, Montana; the 20th was spent at Anaconda; in the latter three places the smelters, etc., being visited. On the 21st, the train left Spokane, Wash.; on the 22nd, Portland, Ore., and on the evening of the 23rd the travellers were met by the Californians and welcomed in the shadow of Mt. Shasta. On the 24th the mines and smelters of the Mountain Copper Co., at Keswick, Shasta Co., Cal., were visited; on the morning of the 25th the visitors and their attendant escort reached San Francisco, and prompt on schedule time, after a trip of over 4000 miles, the session of the Institute began at 1:30 P. M., Sept. 25th, by an address of welcome by W. C. Ralston, on behalf of California, responded to by Jas. Douglas, president of the Institute, who said, in part, that Mr. Ralston's remarks regarding the mining appliances that had been introduced in California recalled the fact that California set the example of automaticity in metallurgy. Continuing, he said:

There is no more perfect piece of automaticity than a gold mill. And I cannot help thinking that it was the example of the gold mill that more or less influenced our iron and steel people to introduce that same principle into their mills, until to-day, from first to last, machinery and not hand power affects all our great metallurgical operations.

This leads me to the subject which I have chosen to address the Institute upon. This is the closing meeting of the Nineteenth century, and it would be inappropriate not to make some reference to the progress that has been made in our special branches during this momentous period of the world's history. I am not competent, nor would time allow, to go into the details of the progress in every branch of mining metallurgy which we ourselves, during our short span of life, have witnessed; but I have chosen to draw attention to some phases of the social bearing of the Nineteenth century on our particular arts, because, as you all know, sociology touches mining metallurgy at a hundred different points. One of the most important phases of Nineteenth century progress has been the liberality with which men, not only of science, but of technical skill, as well, are willing to lend their experience and transfer their thoughts to others. This has been an age of great growth of democracy, and the spirit of democracy has likewise imbued the great population of scientific and technical men until there has grown up to be an actual brotherhood in the secrets of nature and a desire to communicate without stint what we know to our brother men.

Ten years ago I believe that we would not have been admitted to the works of the Boston-Montana Co. or the great works of the Anaconda Co. or the Keswick works; but this noble feeling of brotherhood in the resources of nature has grown and is growing every day. We have already sent that spirit abroad in the world, and that spirit will continue to pervade the world until it absolutely absorbs it, and there shall be no secret which one man knows which he will not be willing to communicate to another. I believe the true progress will not be made until this comes. When we look back upon the last half century, I think we will find that those arts which have progressed the most rapidly have been those which that spirit has most thoroughly permeated.

That man stands highest in his profession who he is willing to communicate to his brethren the largest amount of scientific knowledge and the greatest amount of what were originally technical secrets. The reason that there was a difference in the progress to-day, just as in the days of trade secrets, was because the real element of success was a personal equivalent, not depending upon the number of facts that a man knew. One man progressed and another receded because one brought business tact, imagination and marvelous foresight to bear upon his business, while the other brought nothing. Upon the great principle of reciprocity depended all recent progress. Only generous givers were thoroughly receptive.

Looking beyond this, which, after all, is more or less a moral influence, we cannot help recognizing that the great force at work during the latter half of this century has been the use of machinery instead of hand power, and that we, as an industrial group of the world's nations, have been the one to have used most this new principle in human affairs. If we look back to the beginning of this century, we can hardly conceive what an insignificant factor we were, economically, in the world's history.

In 1840 we had something over 2000 miles of railroad, and 801 little blast furnaces all over the country, each making one ton of pig iron a day. Now, if we multiply the number of tons of pig iron that those little blast furnaces made in 1840 by forty, and multiply the number of miles of railroad that were then in existence by the same number, we get almost exactly the number of tons of pig iron that are made to-day and the number of miles of railroad by which we are hurried here and there over the country. It may seem odd, but it is the fact that this extraordinary progress of the iron industry and the progress of railroad building have run on absolutely parallel lines, with but few deviations. Owing to cheap transportation the iron ores are now transported a thousand miles or more to the coal. All the little centers of industry

have slowly died, and instead of them great central establishments have been located, where, by dint of machinery, iron and steel are made at figures that we ourselves, less than a generation ago, could not conceive to have been possible.

The natural resources of no one country are going to avail her to win the race of industrial progress. If in the future we are to stand on the topmost pinnacle it must be by bringing scientific research, technical skill and mother wit to bear upon our great industries, just as we have done in the past. We are free in a great measure from Old World prejudices. When we are free, likewise, from Old World sympathies, which have had a tremendous retarding influence upon Old World institutions, the end will have been attained.

In all these respects, gentlemen, I think we have had notable advantages over the Old World. But we are teaching them, just as they have taught us, and in the future we may rest assured that they will, sooner or later, learn the lesson and hoist us with our own petards. The twentieth century will see a race again between the Old World and the New World for, I will not say supremacy, but for prominence in all the industrial arts. We will hold our own, not by the possession of natural resources, but by the possession of that marvelous mother wit which we have already brought to bear on what we have done in the nineteenth century.

Prof. W. P. Blake read a technical article on "The Origin of the Yosemite, Cal., Valley, and the Erosive Effect of Glaciers." In the course of his remarks he said:

The gorge of the Yosemite, so grand and impressive, is only a minor feature of the glacial workings above it, through hundreds of square miles of the Sierra. The ice has left its record in the Yosemite, even to the floor. The ice must have filled the gorge, and much above it, to a thickness of 5000 feet, and with a pressure upon the floor of the valley of 120,000 pounds to the square foot. Imagine the tremendous force of such a weight, on the under surface of which was a broken mass of rock, like diamonds in a drill, grinding, planing and cutting. For untold ages this mighty force was at work, polishing the face of the country through which it passed. The character of the rock of the Yosemite is granite, close-grained and vertical in structure, with points of easy fracture. As the great mass of ice bore down upon this vertical rock, it was broken and knocked over by the moving ice, flaking off at the places of easy cleavage. Thus was formed the precipice and thus is explained the dome-shaped summits of the mountains there. The ice has left its track unmistakably.

It has been argued against the glacial theory of the formation of Yosemite that no glacial moraine is found in the valley. We have the testimony of many scholars that glacial moraines are not found where a glacier debouches into a lake or the sea. We know that the ocean once beat against the foothills of the Sierra, and it is by no means impossible that the sea once reached as far as the outlet of the Yosemite. The polishing effect of great masses of ice, seen beyond question of doubt in many high places in the Sierra, is removed in many other places by the storms and frosts of ages. Yet no one can visit Yosemite valley without perceiving evidences of glacial action. The theory advanced by Professor Whitney to the effect that there was a tremendous convulsion of nature in which the floor of the valley sunk below the level of the surrounding hills, thus accounting for the precipitous cliffs, is entitled to fair consideration, but it does not account for the glacial action seen on every hand.

In crossing the Sierra from the Yosemite to Lake Mono the evidences of glacial action are shown on every hand. There, on the Tuolumne meadows, are the rounded tops of hills over which swept in bygone ages vast masses of ice, which must have covered the Yosemite valley hundreds of feet. As this mass pressed forward, grinding, crushing, smoothing and shaping, evidences were left behind by which the geologist may read the record as plainly as in an open book. The rocks are there in places exactly as left by the disappearing ice. In one place the ground has been smoothed—sandpapered, so to speak—by the gigantic force, so as to be dangerous to animals and has earned the name of Bloody canyon.

"Notes on Mining Cable Tests and Physical Tests of California Timbers," was the next paper, by Prof. Frank Soule of the University of California, followed by one on the "Construction of the La Grange Dam," by E. H. Barton of Sonora, Cal., both in abstract. Other papers, presented in print, were: "Stoping With Machine Drills," Bert. Thane, Sumdum Chief mine, Alaska; "Deep Mining at the Utica," J. H. Collier, Tesla, Cal.; "Note on Plate Amalgamation," Allan J. Clark, Lead, South Dakota; "The Mines and Mill of the Atacama Mineral Co., Ltd., Taltal, Chile," Sydney H. Loram, Chingford, Essex, England; "Investigation of Magnetic Ores from Eastern Ontario," Frederick J. Pope, New York City; "The Relative Desulphurizing Effect of Lime and Magnesia in the Iron Blast Furnace," O. R Foster, Brooklyn, New York, which closed the first day's session. Mr. Clark's paper on plate amalgamation is herewith presented in full:

In his paper on "The Accumulation of Amalgam on Copper Plates," R. T. Bayliss records the fact that at the Drumlummon mill, at Marysville, Mont., a series of tests proved that silver, instead of showing a strong affinity with the amalgamatad surface of the copper plates, gave evidence of a persistent tendency to escape amalgamation; the fineness of the amalgam, as measured in gold, being highest nearest to the battery, and giving place to a constantly increasing proportion of silver as the amalgam was deposited upon the copper plates at greater distances from the battery discharge.

On reading this paper during the summer of 1897, it occurred to my mind that the extremely large plate surface presented in the mills of the Homestake Company would offer almost ideal conditions for the observation of this phenomenon. With this object in view, the experiments recorded in Table I were conducted.

In view of Prof. Hofman's exhaustive description of the Homestake milling practice, only a brief summary of the conditions of the test will be necessary.

All the samples were taken from the Golden Star mill—a full series on the same day. In several cases more than one sample was taken, but the results always coincided very closely with those given in the table.

The pulp from the battery was in contact with the following amalgamating surfaces:

1. The inside plate of copper.
2. The "first row" plate of copper, 12 feet by 4 feet 6 inches in size.
3. The "second row" plate of copper, plated with one ounce of silver to the square foot, and 12 feet by 4 feet 6 inches in size.
4. The "third row" plate of copper, same as the second row.
5. The "fourth row" plate of copper, same as the second row.

At the period of the experiments the plates of the last three rows had been in service for about one year.

The results of these experiments apparently confirmed Mr. Bayliss' experience in every detail. At least, that was the writer's conclusion; and he thought no more of the matter until, during the first months of 1899, another series of analyses, undertaken with another object in view, brought the subject again to mind.

During the interval—to be more exact, in July and August, 1899—the plates of the second, third and fourth rows were taken up, thoroughly cleaned, and replated at the works with two ounces of silver to the square foot. They had, therefore, been in use about six months at the period of the new tests, and were in perfect condition. These assays were not made from small samples, but from the entire product of the plates of four batteries during a period of three months, assays being made after each semi-monthly retorting during this period.

The results are recorded in Table II. As will be noticed, these figures are an absolute contradiction of those previously obtained.

It is with the hope of eliciting discussion from the members of the Institute, and perhaps learning of similar experiences, that this note is written.

To the writer it would appear that the following is a probable explanation, though he must admit that it is pure theorizing on his part, and that he can bring forward no authorities to support his view.

In the first tests the silvered plates, carrying but a light deposit of silver when put down, and having been in service for a considerable time, must have lost a considerable amount of their silver, and must have been approaching the condition of the plain copper plates; while, in the second series, the heavier silver deposit and the shorter service make it certain that the silvered surface was intact. It would seem, therefore, that the explanation must rest upon the amalgamated surface—copper in the one case, and silver in the other; and that the tendency of the silver in the pulp to resist amalgamation decreases, if it does not entirely disappear, when thoroughly silver-plated surfaces are used in amalgamating.

TABLE I.—TESTS MADE IN 1897.

Sample From	Fineness. Gold.	Fineness. Silver.	Ratio of Gold to Silver.	Remarks.
Inside plate	.818	168	4 87 to 1	
Copper plate, 1st row	.812	175	4.65	
Silvered plate, 2nd row	.654	331	1.97	
Silvered plate, 3rd row	.618	376	1.64	
Silvered plate, 4th row	.512	465	1.10	
Copper plate, head of 1st row	.809	180	4.49	These are somewhat below the average values for 1st row amalgam.
Copper plate, foot of 1st row	.784	185	4.14	

Difference in average gold-fineness between 2nd and 4th rows, 141.

TABLE II.—TESTS MADE IN 1899.

Sample From	Highest Gold. Fineness.	Highest Silver.	Lowest Gold.	Lowest Silver.	Aver'e Gold.	Aver'e Silver.	Aver'e Ratio.
Silvered plate, 2d row	.573	429	558	408	564	421	1.34

Silvered plate, 4th row	.566	452	542	425	558	433	1.29

Difference in average gold-fineness between 2nd and 4th rows, 6.

"Stoping With Machine Drills," by Bert Thane of the Sumdum Chief, Alaska, mine, was treated as follows:

The mining industry has, within the past few years, taken a new impetus in all its branches. New mines are being opened every day, while old ones, which have been either working at a loss or have been compelled to shut down, are now gradually being reopened and placed on a paying basis.

This growth and new life are due, in a measure, to the discovery of new mining districts, but the most important cause of the progress is the wonderful advance that has been made in all branches of engineering.

By means of the important inventions and discoveries that have been made in mechanics, chemistry and electricity, we are now able to work ores which, only a short time ago, would have been regarded as worthless. We find, for instance, the electrician eliminating two of our greatest difficulties—those of distance and superior elevation—while the mechanic has brought to the highest degree of perfection not only ore crushing and hoisting machinery, but all such devices as pertain to the mechanical handling of ores. At the same time the metallurgist, with his combined chemical and mechanical skill, has helped us to extract the precious metals from the most refractory of ores.

But, when we turn to examine methods in actual use for actually mining or breaking ore, we are surprised at the small amount of progress that has been made in this direction. In the handling of the ore after it is broken, almost everything has been done to reduce the operation to its simplest and cheapest mechanical form, and every form of engineering skill has been brought to bear upon the problem. But the work of the engineer usually ends with the erection and installation of the machinery that he has designed. His interest rarely reaches to the details of breaking ore; this is supposed to be the peculiar province of hand labor. This branch of the business is usually under the immediate supervision of men risen directly from the ranks, who have learned to do exactly what was done before them, and, accepting without question that this is the only method, have bent their energies to bringing that method to the highest degree of perfection.

There is no intention of denying the value of such work, for it is done well, and the energy, the system and the skill with which it is carried on are all of the highest order. But this does not prevent one who has marked the revolution which mechanical devices have wrought in other branches of mining from wishing to see the proper appliances brought to bear upon the problem of breaking ore.

The use of power drills in stoping is one of the methods that have been proposed to meet the problem. Although their use for this purpose is not new, the method has not, in my opinion, received the consideration that it merits. We find the big machine in the shafts, tunnels and drifts a decided success and in use almost everywhere; but when we look for "the little one" in the stopes and on the vein, we find instead the miner and his hammer pounding away, just as his fathers did before him. Perhaps I should make some exceptions here and mention what has already been done in this line, but it has been so little, especially in this country, that it is hardly worth mentioning.

Attempts have been made to use machine drills in stoping from time to time by enterprising men. Most of these, from one reason or another, have resulted in failures; and a failure once made is sure to be heralded far and wide, only to be lived down by the slow growth of success.

It was through the failure, or rather the repeated failure and final success of one of these attempts that I personally witnessed, that caused me to become personally interested in this subject; and, as it bears directly upon the question before us, I will endeavor to give a short outline of my experiences and their results.

While working underground in the Chief mine at Sumdum, Alaska, I had the good fortune of being placed as helper, or "chuck man," on one of these small machines, known as a "Baby Ingersoll." It was used for stoping and raising on the vein. It was, therefore, an excellent example of the problem before us, as the vein varied from 1 to 3 feet in width, the most unfavorable for machine work; besides, the place of working was one of great difficulty, as it lay along the shaft, making any mistakes dangerous and costly. Thanks to my partner, who was a machine man par excellence, no such mistakes were made.

This was the fourth attempt to use the little drill at the mine and the first to register a success. My partner, who was a late arrival from the Cœur d'Alenes, found the little drill thrown aside in disgrace, and covered with rubbish. But he knew what it could do, and begged to be allowed to give it one more trial.

Of course, it is out of the question to use the big machine, on account of its size and weight, for stoping in such narrow veins, even though in its own sphere it is already a success.

The cause of failure, in the use of the small drills, was due, in this mine at least, to the fact that the men who had attempted to work them were used to the big machines, where the strength of stroke and large size of the hole overcame many of the difficulties met with by the smaller ones. The latter naturally requires more care and skill, but this care and skill is not so great but that any man of ordinary ability can master it.

The drill used by us weighed 170 pounds when mounted on a tripod. We found the latter to be much better than a bar, as it allows greater freedom of motion—something absolutely necessary in following a hole—and takes much less time in moving from one place and setting up in another. With the machine that we used the bolts are so arranged that a drill may be driven in any direction by a simple manipulation of the legs of the machine, which is easily acquired by practice.

The chief cause of trouble in machine drilling arises from the many "slips" and layers of alternately hard and soft rock, which are found running in every conceivable direction in vein formation. A drill once started, for instance, will run freely till it strikes one of these slips, which it will, naturally, have a tendency to follow; or, again, if driven through soft seams, it comes in contact with harder material and it will immediately begin to slip along the new surface. This tendency, if allowed to continue, will cause the drill to bind against the bend in the hole, and will not only prevent the drill from entering the hole, but will hold it fast and prevent its withdrawal. This not only causes much annoyance and loss of time, but it frequently causes the total loss of a hole.

With a big machine, where the power is sufficiently great, the drill is driven ahead and pulled out regardless of the slips and bends, and this difficulty is more easily surmounted; but with the smaller one, constant watch must be kept, and the instant the drill starts to slip or bind the machine must be readjusted to follow the hole and the stroke shortened, as in starting. To do this it is seldom necessary to stop, for a perfect understanding of the drill, and between the men working it, allows the chuck tender to loosen the proper bolts while the machine is still in motion; and as soon as its position is changed enough to allow it to run smoothly, it is fastened again. From personal experience, I think it is not only unnecessary, but unwise, to attempt to drill holes too deep. This practice is usually the cause of much trouble and loss of time. From 3 to 6 feet is plenty deep enough for such work, generally speaking. This is all the more the case, as the time required to move the machine from one place to another is very small indeed.

A tripod necessitates the use of a platform to work on; but as it is very easy to build one out of lagging, this is a matter of very small consideration, especially as the planks may be used over and over again, and a platform once built saves time in the end, as one can move about freely and rapidly, and with less danger of accident.

So far the economical side of the question has not been mentioned, but simply the practicability of the small machine. With regard to this new side of the question, and a most vital one, it is almost impossible to collect data of any general application, because of the small amount of work that has been done with the small drills up to within the last few years.

However, I am informed by Capt. Thos. Mein, recently superintendent of the Robinson mine, in the South African gold fields, that in this great district the use of small machines on narrow veins is an established fact, and is carried on with great success.

In our own State I find that within the last six months some three plants, of five small machines each, have been put in; that in the North Star at Grass Valley is perhaps the best known.

My own experience with this work is about as follows: With the "baby drill," two men—my partner and myself—were able to drill about 40 feet a day in hard quartz, full of slips and seams. This work was done between the hours of nine and half past four. The rest of the shift was sufficient for us to do all our own timbering, to build our chutes and ladder-ways, to shovel away our broken rock and to keep the place in ship-shape order.

Circumstances favored me in the following way, with an opportunity to compare the machine and hand labor to advantage. During the holidays the compressor was shut down for a week or so, preventing the use of the machines. During this time we worked in the same stope, using now the hammer to drive our holes. The comparison is an excellent one for the following reasons: All the conditions were the same in both methods; the rock was the same throughout, the size of the vein and the nature of the working places were the same for both methods, and, as we were situated away from the other workmen, the quantity of rock broken daily was accurately measured.

The results of the comparison were all in favor of the drill, for we found that for an average of the week's work we were able to break down just half the ground that we did before, in the same time; or, in short, that two men are able, under similar circumstances, to do twice as much work with the machine as they can do by hand. There is also another incidental advantage—that of ventilation. One of the greatest difficulties of the superintendence is to see that the men are properly supplied with fresh air, particularly in making uprises. This difficulty is entirely eliminated when machine drills are used. It must be evident from these considerations that the small machine drill is practical and economical, as far as labor is concerned, when it is properly used.

There still remains the cost of drills, compressors, power and pipe line, etc. It is unnecessary to go into these questions in detail, because each case must be settled by itself, with a full knowledge of the situation, source of power, size of plant, etc. But with an abundance of water power, and the elimination of distance and position made possible through electricity, the running expense for power is very slight, and the first cost of plant is within the reach of any stable company capable of either opening or running a mine. While, therefore, a certain increase of expense for power and plant is necessitated, the reduction in the expense for labor is just one-half as much more than offsets this outlay.

The reduction in the number of hands needed for breaking ore is one of the chief causes of the prejudice that many miners have against the machines. But this prejudice is entirely unwarranted, for every cause that increases the output of the miner and decreases the expense of mining only tends to open new mines, and enables old ones to increase their force, thus giving plenty of work to the supposed surplus of miners.

On my return to the mine I hope to secure further and fuller data on this subject, in order to convince others of what I firmly believe myself, for I think it is only a question of time before we will have the little machine everywhere high up in the stopes, pounding its way into prominence and success.

On the 26th the first paper was one in abstract, on "The Electromotive Force of Metals in Cyanide Solutions," by Prof. S. B. Christy of the University of California, with diagrams illustrated on a screen, followed

y a paper on "Some Features of the Economic eology of Russia," by Prof. A. C. Lawson of the niversity of California. "The New Alaska-Treadell Gold Mills," by Robt. Mein, was the subject of ne next paper, followed by one on "The Peculiar re Deposit of the East Murchison United Gold line, Western Australia," by D. P. Mitchell, Palo lto, Cal., herewith appearing in full:

Western Australia is the home of much that is ew and interesting in the gold-mining industry. ome of the gold deposits are outranked for size and alue by nothing yet discovered, while the value of ne ores is, in many cases, rivaled only by their comlex character. As in all parts of the world, many f the ore bodies occur in ways which tax the skill of he miner in following them; and among these the riter considers the case of the East Murchison nited more interesting than the average. This is ne of the leading gold mines of the colony in point f production, and is situated near the town of Lawrs, in the East Murchison district. The country r several miles around the mine is mainly granite, nd the line of outcrop on which this mine is located an be traced for a long distance. There are, at the ater level, two nearly parallel veins running ightly north of west.

Structural Features.—The most striking peculiarity these veins, and the hardest to understand, is heir tendency to send out horizontal stringers or de veins. These vary in size from a veinlet an inch hick to a vein several feet in width, and they exnd with great persistence into the wall rock on ther side of the vein.

The usual signs of a movement of the wall rocks, ch as a ribbon structure of the quartz and a wellefined gouge or seam of clay along the walls, are in any places lacking, while in other places they ppear strongly marked. They seem more in evience below water level than above.

It is a commonly accepted idea that when a goldearing vein loses in width, it often gains in value. this instance, however, the direct opposite is the se; for in many stopes it has been possible to ave the narrow portions of the vein to act as illars, and to extract only the wide portions, which re of high grade. This reduces the cost of stoping, nd is of advantage in many ways. Although the arrow portions of the vein proper are of low grade, is a strange fact that the stringers, of whatever ze, are usually of high grade, some of the smallest es containing much coarse gold. Their connection ith a narrow portion of the vein seems to make no fference with their capacity for carrying value. The great number of small stringers which branch t from the main ore bodies, in places, were numerus enough to make valuable ore out of what would ve been, except for their presence, worthless wall ck. In other words, they increased the available idth of the stopes by several feet.

Mineralization.—Portions of the veins are heavily harged with iron pyrites, both cubical and massive, nd other portions with galena, usually in a finely sseminated condition. It is a matter worthy of otice that wherever an ore chute is heavily charged ith galena the fineness of the bullion saved by malgamation drops from 5% to 10% below its noral grade. The whitish color of the bullion indicates ainly its decrease in value. The concentrates btained from the ore, after removing the free gold y amalgamation, are of a very high grade, running om $700 to $900 per ton.

In those portions of the vein extending from the rface nearly down to water level, a curious phenomenon is to be observed. This consists of the condary mineralization of the veins, taking the rm of arborescent and massive occurrences of iron nd manganese oxides. These are found along the eavage planes and in cavities throughout the veins, nd are probably derived from the decomposition nd solution of various minerals from the veins and all rocks, and their deposition in these forms. hese secondary deposits, which are almost invariply very rich in gold, mark the superficial enrichent which has taken place in so many of the quartz eins of this colony.* The fact that they do not xtend below water level, or into the zone of sulphide inerals is evidence of their secondary nature.

Influence of Structure on Development.—From delopments on the surface and at water level the eposit seemed to consist of two slightly converging eins having approximately the same dip; but as reater depth was attained an intricate system of oss and horizontal fissuring was revealed. The endency of the veins to become horizontal at times nd to send out horizontal stringers was not at first garded as of much importance, and, consequently, evelopment work was planned on the supposition hat the dip of the veins at water level would conue in depth. When the full significance of the orizontal occurrences was realized, the plan was dopted of sinking winzes to find where the vein ecame flat, and thus indicate where to locate the vels.

The large size and high value of these horizontal portions of the veins render them very valuable additions to the ore reserves. In extracting ore from them, the roof is supported by cribs, locally termed "pig sties," until the whole space can be solidly filled in with waste rock.

* H. C. Hoover has treated this subject at considerable length his paper on "The Superficial Alteration of Western Australian re Deposits:" *Transactions A. I. M. E.*, October, 1898.

"The Occurrence of Tin Ore at Sain Alto, Zacatecas, With Reference to Similar Deposits in San Luis Potosi and Durango, Mexico," was the subject of the next paper, by Edward Halse of Colombia, S. A., followed by one on "The Copper Deposits of Vancouver Island," by Wm. N. Brewer, Victoria, B. C., condensed as follows:

Until within the past two years but little attention has been given to the outcrops of the west coast of Vancouver island and their copper contents. During the past few months the writer has been engaged in examining and developing some of these prospects.

In many respects he has found characteristics associated with these prospects which, in his experience, are unique. Nearly all the outcroppings which overlie chalcopyrite ore along the west coast of the island are composed of a high-grade magnetite. The magnetic qualities of some of these outcrops are so pronounced that the magnetite possesses polarity. Although the writer himself had no analyses of this magnetite made, yet from its appearance he can readily believe that analyses made for other parties, which show a yield of 62% or 63% of metallic iron, with only traces of phosphorus and silica, are correct.

At a very shallow depth masses of chalcopyrite, yielding in some instances as high as 32.6% of copper, occur associated with the magnetite; and in once instance, which recently came under the writer's observation, a solid body of high-grade chalcopyrite fully 4 feet in thickness occurs within 6 feet of the surface.

Usually this solid sulphide ore carries low values in gold. Probably an average of $2 per ton would be fairly representative. But in some instances development has determined the occurrence of narrow stringers of pyritous quartz, associated with the sulphide ores, which yield by assay more than $20 per ton in gold.

In the districts examined by the writer the country rock is usually crystalline limestone, with dykes of igneous rocks as intrusions. Sometimes the outcrops of magnetic iron ore are found in the limestone itself; but they usually occur at the contact between the limestone and igneous rock, or in fissures cutting through the igneous dykes. Most of these dykes are apparently quartz diorite.

The trend of the country rock is conformable with that of the island, *i. e.*, northwesterly; but the line of strike of most of the ore bodies is usually northerly or northeasterly.

As lode mining on Vancouver island is in its infancy, it is impossible to present many facts with regard to these extraordinarily rich outcrops. In fact, 175 feet is the greatest depth which has yet been attained on any of the ore bodies. At another location, recently visited by the writer, he found that high-grade chalcopyrite occurred at a depth of about 120 feet.

Although the outcrops of magnetite are usually persistent in length, especially when they occur in fissures in the igneous dykes, yet the writer has failed to find any instance where the lodes can be traced for any very considerable distance without a break.

On Bear river, at the head of Bodwell sound, some of the outcrops can be traced a distance of 500 to 700 feet. Another instance where the outcrop can be traced for about the same distance occurs on Anderson lake, which empties into Uchucklesit harbor. Still another instance occurs near Goldstream, ten miles northwesterly from Victoria. This last outcrop, however, is composed of gossan instead of solid magnetite.

Usually when the outcrops are found on the contact between the crystalline limestone and igneous rocks they cannot be traced as readily along the line of strike as when they occur in fissures in the igneous dykes. The contact outcrops occur in masses or pockets, sometimes covering a considerable area of ground, and often disposed in a tolerably regular line, but with no indications on the surface that there is any connection between the different pockets.

It is not safe to form an unqualified opinion as to the non-maintenance of continuity along the line of strike, because the ground is often covered with moss or debris from slides. At no location known to the writer, where masses of outcrops occur along the contact, has sufficient underground work been performed to determine the continuity of the ore bodies between the masses of outcrop.

The writer has observed several places where the outcrop of magnetic iron ore occurs in the crystalline limestone. Such occurrences are apparently limited in extent, but impress one that their structure has the same pockety and irregular characteristics as belong to the limonite ore deposits in the Southern States.

So far as the grade of the various outcrops is concerned, the writer has oberved that there is but little, if any, difference between those occurring in the igneous rocks, on the contact, or in the limestone.

Besides the outcrops of chalcopyrite, bornite occurs in some localities, with heavy spar as the gangue. There is such an occurrence on Deer creek, where a fairly high-grade bornite is plentiful at and near the surface; but the writer is informed that as depth has been attained the bornite has given place to chalcopyrite of good grade. Except the deposit on Deer creek, the writer knows of no other discovery where bornite has been found in any quantity to the southeast of Sidney inlet, which is thirty miles up the coast from Clayoquot.

The portions of the island to which the writer has given most attention are in the neighborhood of Goldstream, ten miles from Victoria; the Alberni canal, which connects with Barclay sound 110 miles northwest from Victoria; and the country adjacent to the inlets which connect with Clayoquot sound, about 160 miles northwest from Victoria.

The geology in the sections mentioned is complicated. The rocks around Victoria are chiefly eruptives. To the northwest, near Goldstream, there occurs a wide belt of semi-crystalline slate, slightly graphitic, in places highly metamorphosed, as on Skirt mountain, in which the copper deposits referred to earlier in this paper occur. This belt of slate has a general trend N. 60° W. On the northeast of this belt occur crystalline limestone, granites, diorites and other igneous rocks, which comprise the formations, until the sandstones and conglomerates of the coal measures are encountered near and along the eastern coast of the island.

The mountains on the island vary in altitude from 1000 to 7000 feet. They are covered with a heavy growth of timber and underbrush. Consequently prospecting operations up to the present time have been confined to the immediate vicinity of the shores of the inland waters and streams emptying into them.

Mineral occurs in three zones, each of which has a northwesterly trend, while each mineral deposit has its individual line of strike. The most southerly of these zones is the belt of semi-crystalline slate, which traverses the extreme southern portion of the island from Goldstream to near the headwaters of the San Juan river. This zone furnished, thirty years ago, a considerable amount of placer gold, which was found in the Leach and Sooke rivers and their tributaries. Northeasterly from this belt of slate occurs the main belt of igneous rocks, which, in places, is several miles in width.

On some of the numerous islands in the sounds which connect with the Pacific ocean deposits of magnetite, with some associated copper pyrites, have been discovered; but on none of them, to the writer's knowledge, has there been any extensive development work performed.

The other papers of the session of the 26th were: "Rock Salt in Louisiana," by A. F. Lucas, Lafayette, La.; "The Lee Long-Wall Mining Machine," by H. Foster Bain, Des Moines, Iowa; "Natural Coke of the Santa Clara Coal Field, Sonora, Mexico," by E. T. Dumble, Houston, Texas. and "Transcontinental Railway Lines," by James Douglas of New York City.

The first paper of the morning session of the 27th was one on "Electricity as Applied in California Mining Practice," by Prof. C. L. Cory, University of California; "The Geology of Arizona," was the title of the paper by Prof. Theo. B. Comstock, Los Angeles, Cal.; "Tangential Water Wheels" was read by W. A. Doble of San Francisco, Cal., who was followed by Mr. Sam'l Thomas, who read the last paper of the session regarding "Early History of Anthracite Coal in Connection with the Manufacture of Pig Iron." The following named papers were read by title: "Notes on the Independence Mine at Cripple Creek, Colo.," by T. A. Rickard, Denver; "Gold Mining at Minas Prietas," by E. R. Abadie, Torres, Sonora, Mexico; "Treatment of Oxidized Ores of the Lake View Consols Mine," by J. W. Southerland, Boulder, Western Australia; "The Effect of Heat Treatment Upon the Physical Properties and the Microstructure of Medium-Carbon Steel," by R. G. Morae, Jamaica Plain, Mass.; "Peculiar Forms of Native Gold," by G. F. Kunz, New York City; "The Cement Rocks of Illinois," by J. A. Ede, Spring Valley, Ill.; "The Temperature at Which Ferrous and Calcic Silicates are Formed and the Effect Upon These Temperatures of the Presence of Certain Metallic Oxides," by H. O. Hoffman, Boston, Mass.; "Wolframite Deposits in South Dakota," by A. Forsythe, Rapid City, South Dakota; and "Nickel Steel, a Synopsis of Experiment and Opinion," by D. H. Browne, Cleveland, Ohio. After the usual remarks the meeting adjourned.

Immediately thereafter a party of visitors went to the University of California, thence to the Selby plant of the Selby Smelting & Lead Co. In the evening the San Francisco merchants and the California State Mining Association banqueted the visitors in characteristic style. On the morning of the 28th inst. the party left San Francisco on an itinerary through the interior of California.

Increasing Mill Capacity.

Written for the MINING AND SCIENTIFIC PRESS.

When large capacity is deemed an essential feature in the economy of milling gold ores, and at the same time fine crushing is required to free the gold from its matrix, an auxiliary plant in the form of grinding machinery of some kind, as supplemental to stamps, has been found to give satisfactory results. The ore first introduced to stamps may be crushed through a coarse screen to ½ or ¾ or even ½-inch size, and then sent to grinding mills to be reduced to the necessary fineness. Where stamps are crushing two to four tons daily, the capacity may in this manner be increased to six or twelve tons per stamp and the ore reduced to the necessary fineness without further expense than the necessary additional power to run the grinding mills. As the ore passes from the stamp batteries directly to the grinding mills, no additional men need be employed, and the increase of power required is but a small fraction of the benefit derived from increased capacity of the mill. This grinding of ore, following crushing by stamps, often brightens gold in some ores which are not readily susceptible to amalgamation with quicksilver, rendering them much more free in milling. Where this method of increasing capacity may be adopted, it may be found inadvisable to attempt to amalgamate inside the grinding mills, as the quicksilver may be floured thereby. A grinding mill having a screen through which a continuous discharge takes place is essentially different from a pan such as is employed in silver mills, where the pan is charged with a given quantity of material, which is ground for a certain length of time, when the mullers are raised and the quicksilver added; amalgamation proceeds until completed, when the pan may be discharged and another charge introduced, to be treated in the same manner as the former one. This method cannot be applied to grinding mills having screens.

With reference to the likelihood of the quicksilver to flour in the grinding mill, all ores do not act alike in this respect. Where the grinding mill is fitted with plows, as most of them are, and amalgamation is practiced in the mill, these plows should not be set so close to the bottom as to constantly scrape up the hard amalgam which may form on the bottom of the mill, thereby increasing the likelihood of loss of gold. They should be set sufficiently high, at least, to admit the fingers of the hand between the lower edge of the plow and the bottom of the pan. Where amalgamation is practiced inside the grinding mill, the quantity of water employed is important, and the amount cannot be determined without experiment. A large quantity facilitates discharge, thereby increasing capacity; but it may also discharge gold before it has had a chance to amalgamate; while too small a quantity will retard the discharge of the pulp to such an extent as to cause it to accumulate and overflow. In adjusting these matters the mill man must use good judgment, and the result of his work will tell him the proper amount of water to employ and also the speed at which the grinding mill may safely be run to accomplish the best results. By the adoption of this method, large capacity and high extraction may be attained at minimum cost.

The Creede Mines, South Dakota.

Written for the MINING AND SCIENTIFIC PRESS.

This group of mines, five in number, is situated on Lightning creek, about one mile below the May mine, and nine miles southwest from Custer City, South Dakota. These mines, for the most part, are located in the Potsdam sandstone, which forms a bench or strip of mesa covering about forty acres on the west side of the creek. The north end of these claims runs up on the mountain, where a number of good vertical veins have been opened, disclosing quartz carrying gold and copper of fair grade. These veins, situated on the high ground, are found with walls of slate, with here and there short stretches of hornblende, with a dyke of granite running north and south in near proximity on the west. These veins of quartz, which penetrate the slate formation, are from 4 to 6 feet in width and have not been developed to any great depth. The ore is a good concentrating proposition, and yields by assay from average samples near the surface about $8 per ton in gold, while the percentage of copper has not been ascertained, probably not more than 3%. But it is of the Potsdam formation I would speak more particularly. It will be observed from the foregoing description that there is something peculiar about the situation of this isolated body of Potsdam, resting, apparently, conformably upon the slate beneath, which is its proper position geologically, but butting up against the steep side of a slate mountain, which rises high above the Potsdam and forms its western and northern boundary.

What the experience of others may have been I know not, but being an old miner myself and having prospected in the different mining camps of the West since the early days of 1860, and never having seen an occurrence of this kind before, it struck me as being peculiar. I remark that the situation of the Potsdam below the old micaceous slate, locally, is new to me, and yet, when I come to view the lay of the land just as it is, I find no difficulty in accounting for the situation, or at least forming an opinion (whether it be orthodox or not), which is satisfactory to myself. I judge from the indications that the upheaval of the igneous granite dyke has created the mountain ridge of slate and that this occurred prior to the sedimentary deposit which forms the different strata of the Cambrian. The flow of water down Lightning creek has been immense at some previous age; the canyon is deep and it has been cut through the solid slate, bringing the silts and sands derived from eroded quartz veins and deposited those sands at this spot where the conformation of the mountain compelled a whirling eddy and here the heavier sediments found a resting place.

I am aware that some geologists whose knowledge of the earth's crust is more profound than mine have expressed an opinion that all of the igneous upheaval has occurred since the laying down of the Potsdam; that all of the different strata of the Cambrian, clear up to the Carboniferous, was formed before the upheaval of the igneous flow. But with all due difference to them, I can not, while gazing on this scene, accept that theory; at least I must insist that this little spot of earth (if no other) forms an exception to the rule, in the Black Hills of Dakota.

Do you ask if this Potsdam formation is metal bearing? I answer yes, to a very encouraging degree. There are vertical cores coming up through the different flat strata, and in some of the layers which are more open to receive or absorb mineral in solution, there have been formed wide shoots of ore. From some of these shoots which have been tested, returns have been received showing as high as $50 in gold and 16% lead. In this I note another peculiarity, for it is unusual (according to my experience) for lead and gold to combine to this extent, where there is practically no silver, and the lead is not in the form of galena or carbonate, but has been pronounced a telluride of lead carrying gold.

C. W. ROBBINS.

Custer City, S. D., Sept. 19th, '99.

The International Congresses of the Exposition of 1900.

Congress of Mines and Metallurgy.—An international congress on questions concerning mines and metallurgy will be held from the 18th to the 23rd of June, 1900, in connection with the Paris Universal Exposition. Like similar reunions at the Paris Expositions of 1878 and 1889, the congress has been organized at the initiative and under the direct patronage of the French Government. In 1878 there were 200 members; in 1889 more than 600, from all the leading countries in the mining industry. For 1900 a great effort is being made to secure a representative assembly of the world's engineers and manufacturers who are interested in the progress of mines and metallurgy.

The members of the congress who will receive all its publications are to be the delegates of the French state departments and of foreign governments, donors of at least 50 francs, and the active members, whose subscription has been fixed at 20 francs.

The public sessions will be held in the afternoon, alternating between questions of mines and metallurgy. Reports on the questions presented for discussion will be prepared beforehand by engineers of the different countries and distributed to the members of the congress.

Each morning the members in groups, under the guidance of engineers and manufacturers specially chosen for the purpose, will study in detail the most notable mining and metallurgical exhibits of the different countries in the Exposition. This common study of improvements realized up to date is to aid the work of the congress in preparing the way for further progress.

The organizing committee is particularly anxious to know, at as early a date as possible, the probable number of active members.

The following questions are provisionally indicated as the basis of the final programme, which will be published when the international organization of the congress is completed:

1. *Mines.*—First, use of explosives in mines; second, use of electricity; third, working conditions at great depths; fourth, means of reducing manual labor in the mining industry.

2. *Metallurgy.*—First, progress of iron and steel metallurgy since 1889; second, applications of electricity to metallurgy: (*a*) chemical applications, (*b*) mechanical applications; third, progress of gold metallurgy; fourth, recent improvements in the mechanical improvement of ores.

The president of the committee of organization is M. Haton de la Groupillierre, director of the Higher National School of Mines. On the committee are represented all the mining and engineering schools and the principal mining and metallurgical companies of France. The secretary general of the congress is the secretary of the Central Committee of the Coal Works of France, M. Gruner, 55 Rue de Chateaudun, Paris.

Gold-Bearing Sands of Vermillion River.*

By J. W. EVANS, M. E., Sudbury, Ont.

The alluvial deposits of gold-bearing sand found along the banks of the Vermillion river, in the district of Nipissing, created considerable excitement last spring and summer, but owing to the character of the gold the results obtained from a few primitive tests were far from satisfactory. In this paper I wish to draw attention to a few points which came under my observation.

In the majority of the deposits the gold is found in the first 10 or 12 inches of soil, a reddish sand composed of quartz, granite and greenstone, containing garnet and magnetic iron, with a quantity of coarse gravel, covered in patches with hardened clay. Samples of this sand from the east bank of the river, in Hanmer township, within twenty miles of Sudbury, averaged from six samples 60 cents per ton gold, and yielded, with very careful panning, from 100 to 200 colors to a ten-pound pan.

The colors vary greatly in size. The larger ones, being flat and much indented, are very liable to float off in panning or washing, owing to minute air bubbles adhering to the indentations. I have frequently lost these larger colors when panning from one pan into another, even when exercising the greatest care.

A few panning results from samples taken to the depth of 2 to 3 feet I have mounted upon slides for the microscope in order to show the variations in size and character of the colors. The average fire assay result on this lot was about 15 cents per ton, the number of colors varying from forty to eighty per ten-pound pan. As an example of the loss in treating the sand with a rocker, I found on selected material assaying $1.15 per ton that the washed coarse gravel which had been thrown out of the screen yielded, upon panning and breaking up the hardened clay sticking to it, twenty colors, which had remained attached to the clay, and assayed 45 cents per ton of gravel, or 25 cents per ton of sand taken. The tailings which were being washed into the river assayed 40 cents per ton of tailings, or about 15 cents per ton of sand taken, and the concentrates from the rocker 80 cents per ton of concentrates, or about 10 cents per ton of sand. The sand taken was from 10 inches from the surface. The fire assay being $1.15 per ton leaves 65 cents unaccounted for, but as the sand contains galena, copper pyrites and some gold-bearing quartz, a higher result in the fire assay is to be expected.

The fire assay results, without previous concentration, however, I find very variable on this work. For instance, taking 100 colors to a ten-pound pan, there will be only three colors, on an average, in a five A. T. charge, assuming the sampling perfect, and as there is a great difference in the size of the colors the results are bound to vary greatly. In a five A. T. charge an error in weight of gold will be multiplied 6400 times in calculating to a ton, while in a ten-pound lot will be multiplied only 200 times. This will in a great measure offset the loss in panning.

The loss in ordinary panning on this sand I put down as about 50%, but with proper care about 75% of the gold can be saved.

I found in every case where I passed the gravel through the crusher and assayed the pulp the results were higher than when the coarse gravel was screened out, proper allowance, of course, being made for the percentage of gravel. In one shaft which had been sunk to a depth of 60 feet, about 200 feet from the river bank, no gold was found after leaving the surface layer until within about 10 feet from the bottom, but from trouble with water the shaft was not sunk any farther, and in no instance, to my knowledge, has bedrock been reached. Owing to the slight fall and thickly wooded nature of the country, sluicing on a large scale would be difficult if not impossible.

Gold has been discovered in many places farther up the river, and in almost every case the gold gets coarser as one goes north.

On one slide I have mounted a facsimile of the largest color yet found on the river. It comes from some distance to the north. The gold found so far is not much worn and the microscope shows pieces of quartz attached to many of the colors.

The sand on the hillside several hundred feet from the river bank gives almost the same result as that nearer the river, and as the course of the present stream is very sinuous it suggests the existence there of a much larger river at some time in the past. I think it very probable that some valuable deposits containing coarse gold will be found upon this river in the near future, and that many of those already found could be worked at a profit on a large scale, in some manner similar to the dredge work done on low-grade placer deposits in California.

The Forest Problem in the West.

By ABBOT KINNEY, of La Manda Park, at the recent meeting of the American Forestry Association at Los Angeles, Cal.

The economic interest of the American people in their forests everywhere, and especially in the West, is to preserve the integrity and water-holding power of the mountain watersheds of the country. This is clearly the public interest, whether these mountain watersheds could or could not support by their products and wise use a system of management guaranteeing the integrity of the water-holding power. The public interest is both economic and humanitarian in preserving the mountain forest covering. Without forest preservation most of our remaining wild public land districts cannot be settled, and districts already settled are likely to lose in man-sustaining power. This has occurred already over wide areas of the world from undue forest denudation, on the one side by the irregular or exhausted water supply and on the other by the destructive action of flood and torrent through sudden rainfall delivery from bared areas. The proper preservation of forest balance does not require that ripe timber should not be cut, or that other uses, such as mining, should not be enjoyed.

Local Considerations.—The interest and requirements of districts vary in what treatment of forested areas is most advantageous. In most of the West and in all of the Southwest the conditions of topography, rainfall and climate exact the highest care and treatment of the comparatively small forested area, all of which in the Southwest is on mountains or high plateaus only.

In this district it were better, for the country and for its people, that no use should be made of forest lands or forest products than to have the forests wasted and burned as at present is generally being done.

However, no such drastic remedy as the isolation of the forests from human use is necessary. Under a proper and intelligent forest system the integrity of the watersheds can be safely maintained, and yet plenty of use can be found for both land and products, uses that can go on without fatal results to the forested area.

It is only in the extreme southwestern mountains that the conditions are such as to counter-indicate the cutting of any timber or even firewood in the mountains. But even here mining, resorts, power companies and irrigation works can be established with no disadvantage to the trees or chaparral, but rather to their increased safety. The nation can gain by preserving its forests in safe proportion, and can in no way consent to see this proportion of safety to its people diminished. The nation will gain by forest preservation even though the system be without any resources or power of self-sustenance.

Special Issue in the Southwest.—While forestry has become a living issue in the Atlantic States, through the depletion of perennial flow of springs and streams and increased flood action, and probably by greater and increasingly injurious extremes of frost and heat arising from forest destruction, in the West and Southwest effective forestry is a question of life or death.

With irrigated districts, present or prospective, the conservation of the forest natural reservoirs is at least as important as the conservation of any part of the rainfall by artificial storage diversion or distributing systems.

The lands on the mountains and watersheds in this part of the United States are in large part Federal public lands. By the extensive reservation of forested mountain lands from sale or settlement, the Federal Government has committed itself to a rational forest system. What the situation demands and what the people desire is a forest management of these important mountain waterseds that will serve the highest interests of the entire community. Interests built up under the neglect and waste and abuses of the Government's forestal mistakes and laches should be treated with all the consideration that the safety of the communities affected and the welfare of the great majority of the people will permit.

All foresters, and especially all foresters in the Southwest, endorse, and must endorse a Federal forest policy, whether the forest management pays its way or not.

The Government forestry systems of European nations, of Canada, Algiers, India and Australia, are self-sustaining, and for the most part bring in considerable revenues. Curiously enough, it is in the countries like Spain, Arabia, Persia and Turkey in which forestry is neglected, where national productive power has most diminished, and in which both nation and people individually are poorest. The success of other countries in maintaining national forest systems invites our attention to this subject.

The principal revenue from all forest systems is from the sale of forest products. These are mainly merchantable timber and fuel. The Western districts in which the principal areas of public lands exist, are situated so that one part or another of California would resemble their conditions closely enough for preliminary plans and outlines of forest management appropriate for the entire Western public land areas.

California's Forest Area —California contains mountains and plains, valleys, farm lands and deserts. In the northwest its climate is one of if not the moistest in the United States; in the southeast it is one of the most arid. In the redwood belt there is a very large rainfall, and almost continuous fog and mist between the rainy seasons. In the Cocopah desert years pass without a drop of rain, or even a cloudy day. California conditions, carefully considered, can do much to outline a forest and public land policy. What is the public land situation here?

California contains 99,361,083 acres of land, of which

The area appropriated is	40,392,418	acres
The area unappropriated is	43,841,944	"
The area reserved is	15,127,621	"
	99,361,083	"

This gives a substantially accurate picture of our land situation. In the other Western States the public lands are in much larger proportion.

The above figures, however, do not give the exact facts. Of the appropriated area some has gone to the State for taxes. In some of the mountain counties this tax area is quite considerable. The State Comptroller and the county officers thus far have found no general record of this tax land, therefore no one can tell to what it amounts.

Of the area reserved, a considerable part is patented and in private hands. In some reserved districts the proportion of private holdings is large, in others very small.

The National Yosemite Park, of about one million acres area, is a little more than half in private hands. The San Gabriel reserve, from the Cajon west, has a very small proportionate area in private hands, while the San Bernardino part of the forest reserves of the south has a considerable area in private hands.

The reserve system suggests the policy of Switzerland. In that republic experience has demonstrated the immediate and often awful results of forest denudation on steep, high mountains to lower agricultural lands.

From this experience has been evolved a forest system which lays out, as a part of its functions, forest reserve districts. The lands within these, whether public or private, are under public control, and not a tree can be cut without public authority. We may come to this system some day.

Public and Private Lands.—There are in this State about 83,000 square miles of public lands in the hands of the Federal Government. An examination made by expert civil engineers on section lines, and mapped by the old State Board of Forestry, shows in its report that the mountain land with merchantable timber is substantially all in private hands. There is, speaking generally, no timber of merchantable quality and accessibility in California not in private hands.

Fuel and small wood costs more to bring out of the high Sierras at present than it will bring. There are restricted districts where the waste and fallen wood or small standing timber could pay its way for use as ties, posts, fuel or mining, but no large revenue is in sight from this source at present. Consequently, the source of revenue and support of foreign systems is absent in California.

We may assume that the known conditions in California in this respect in one or another of its districts apply to those of the entire West.

There is, however, a source of revenue to the Government from a rational management of its mountain forest lands, when handled in conjunction with the development of public irrigation works of the vast area of arid public land.

The reason why there is such a large amount of public land in California and in the West generally is that the land is all in an arid climate, and that it is therefore incapable of supporting a farmer or settler, without a secure supply of water for irrigation, and often for domestic use.

Forests and Irrigation. — The mountain forested areas are all incapable of agriculture in the Southwest. There is consequently no gain of productive area, as in the settlement of Ohio, for instance, by denuding them. On the other hand, these forests are the natural reservoirs of the Southwest.

The forests in this section are of the highest importance both to the irrigation districts already developed, and also to the enormous areas that may by future irrigation works be made fertile.

Storage reservoirs, diversion works, ditches, etc., are all safer and more permanent when under a forested watershed than under a bare one. In the first case, with forest covering, there is a minimum of flood action, and practically no torrential detritus to fill up the works. From a denuded watershed the water delivery is irregular, torrential and detritus-laden.

The public land now at its limits, or near its limits of support of population, can, by judicious irrigation works, be made capable of supporting a population of between fifty and one hundred millions. Irrigated land has always been as capable as that for supporting the densest population from agricultural returns. We see this in the history of the Euphrates and the Nile. In both of these cases, and in the more modern developments in India, we see that the important works were carried out by the community or Government, were managed by the community, are thus managed, and that new work for further development in the application of water to land in genial and dry climates, such as those of India and Egypt, is planned or being executed solely as Government undertakings.

Why the Government Should do it.—There are three good reasons with us for this policy. The first is that the lands susceptible of improvement are largely public lands. The second is that the undertakings are too large for most private initiative, and the third is that a public administration of irrigated lands is the only one in which the land occupants can feel safe in not becoming serfs of the water company, as is now practically the case in the rich, irrigated valley of the Po, where the returns are large, but the people in misery.

Governments in the past and governments now recognize the advantage and propriety of making their lands productive by public irrigation works. The peoples who have done this in the past have been among the greatest. One of the most powerful governments of the present day, that of Great Britain, is now, as it long has been, engaged in such irrigation development. The dam on the River Nile, near Assouan, will be the greatest land reclamation work in the world. The values created by the application of water to land in Egypt will far exceed the values created by the exclusion of water from land in Holland. Both are Government undertakings.

Other Government Work.—In this country the Government has undertaken land reclamation by exclud ing water, as by the Mississippi dykes. It has also added to the land values and product values by the construction of harbors and canals, thus reducing or removing freight tariffs or lighterage and landing tariffs. The States on or having rivers have been benefited by this policy. So also the coast States or those on the lakes or served by the great Sault Ste. Marie canal have been benefited; so has the country generally been benefited.

It is eminently proper that the people's Government should apply this policy to the development of the rich and sunny Western lands that cannot produce and serve mankind without water. In this case the benefit is direct to the public. It is homes for the people that will be created. It is, of course, markets and a high productive-power population in our own bounds that we thus create. It is the conservative agriculturist that we thus introduce and encourage to balance the more radical bodies of employes in the great manufacturing districts. Fifty million such Americans will consume more American products and support more American trade than all our present foreign trade combined.

Taking the public land area as a whole we find some that is inherently worthless, some that can be made good and productive, some where forests and their products can be safely used under reasonable regulations, some where the forests can only be safeguarded but not used, as in the chaparral mountains of the South, and a wide district that is at present used for pasturage, excessive and premature. The pastures thus deteriorate and carry less stock.

Forest Lands Should be Leased with Proper Regulations.—The public land pastures have deteriorated and are deteriorating in stock and sheep-carrying power. Fighting and disorder is everywhere present among the pasture users. Sometimes they have wars. These stock and sheep men, as far as seen, welcomed a proposed system of leasing the public lands appropriate to pasture, under judicious restriction as to the number of stock permitted on each section and the time of year when the stock should go on. The public lands in California have a present value for pasturage that varies with seasons. It is estimated to have an annual rental value of not less than $250,000 and may exceed half a million dollars. Its rental value varies with the seasonal rainfall. The stockmen would be glad to pay rent and thus know upon what feed they could rely, without the present accompaniments of murder and arson.

These districts where pasturage injures the watersheds could have the stock reduced to a safe number by reasonable regulation or entirely removed.

When we consider the vital importance of the entire forest question, and past and present precedent in the matter of forestry and irrigation; when we consider the effect of forest denudation in filling up navigable rivers and harbors, the importance of water to miners, to cities and to irrigators; when we further reflect on the empire at our hand and in our borders to be created by irrigation works, we can agree that forests, reservoirs and public land management all go hand in hand.

The land system as a unit can be self-supporting and revenue-producing. All interests can be fairly dealt with and the country brought to its highest productive power.

Those who engage in promoting this great work have strenuous efforts before them; they deserve the garlands of reward as civic patriots as much or more than those who foment distant foreign wars. The conquest of this empire within our bounds for our own children is more useful, more profitable, more secure and more glorious than any foreign conquests can ever be.

Mine Exploration by Diamond Drill.

The M. C. Bullock Manufacturing Co., 1170 West Lake street, Chicago, Ill., have issued a treatise on the diamond drill, which is of sufficiently practical a nature to deserve extended extract therefrom. As stated, the development of a mineral property depends largely upon its having been prospected carefully and intelligently, and the later operations planned and executed with a knowledge of the extent, character and trend of the ore bodies. Prospecting with the diamond drill, equipped not only for extracting cores, giving a sample for assay, but also for indicating the character and extent of loose and caving material, is often the quickest and cheapest method of determining the value of a mine.

The boring tools used in diamond drill work are shown on page 369, as illustrated in the pamphlet to which reference is made.

Bit blanks (Fig. 1) are made from a solid bar of homogeneous steel. The bit blanks are made with an outside shoulder and a counterbore, giving ample waterway to the face of the bit.

The solid bit (Fig. 2) is used in drilling through a large body of barren rock which is underlaid with a mineral deposit. It is often the cheaper plan to use a solid bit and cut away all of the rock overlying the mineral, than to use the core bit and lose the time required in withdrawing the rods and taking the core from the core barrel. The core bit is set with diamonds in the ordinary manner, then the "plug" center, also set with diamonds, is inserted, and this combination makes an effective solid bit. After the barren rock has been penetrated the "plug" center is removed and the drilling proceeded with in the ordinary manner, extracting a core from the ore-bearing formations.

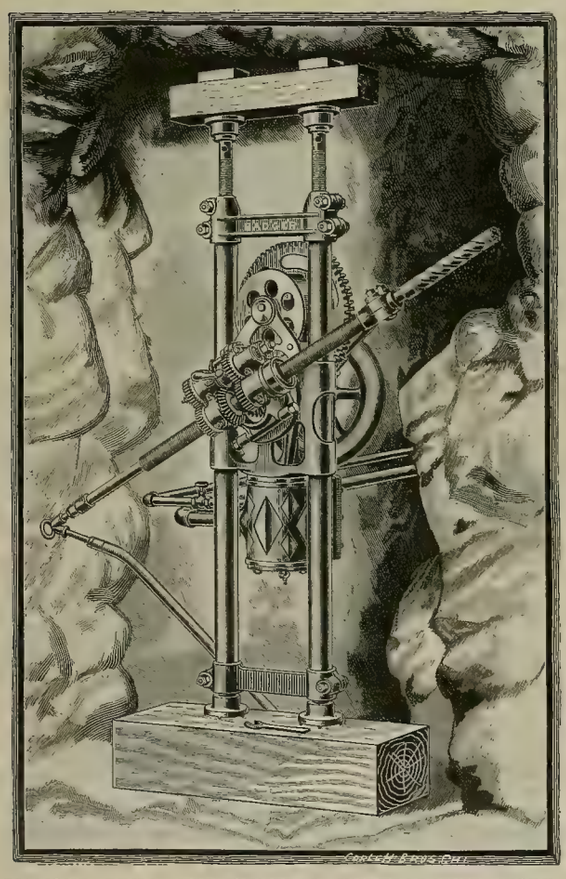
Core lifters (Fig. 3) consist of three parts—shell, ring and coupling. The shell is bored with an inside taper, into which fits the split ring or spring (Fig. 4). As shown in the illustration, this ring is wedge-shaped with inwardly projecting lugs, which grip the core when under compression. The coupling is screwed into the top of the shell and acts as an upper stop to the ring. The shell and ring being tapered, when the ring is in the upper end of the shell, it is loose and under no compression, but when it is pressed down to the bottom of the shell, the effect of the double wedge is secured and the ring is brought under heavy compression and contracted so that it grips the core tightly. In operation the ring does not rotate with the shell, but rides lightly on the core, sliding down—not under compression—as the bit advances into the rock. When the "run" has been made and the rods are hoisted, the first lift of ⅛" draws the core lifter shell upward, so that the ring is compressed and grips the core, breaking it off close to the bottom and bringing it to the surface. For boring in very soft ground, the ring is made smooth inside and of extra length.

Core barrels (Fig. 5) are made of cold-drawn seamless steel tubing, with the spiral water tubing grooves cut on the outside. This permits of making the core barrel of almost the exact diameter of the hole, so that it acts as a guide and keeps the hole straight. In drilling at an angle across formations which alternate hard and soft, this core barrel prevents the bit from deflecting and following the softer stratum. In crosscutting the formations squarely, the plain core barrel can be used, but as it is made of a slightly smaller diameter than the bore hole, to give a sufficient water space, it does not act so effectively as a guide to the bit as the spiraled core barrel.

Drill rods are made of lap-weld steel tubing, fitted with a coupling, which gives uniform strength to the line of rods (Fig. 6). The rods are cut to exact length, 5 feet for underground and 10 feet for surface work, and accurately threaded, so that the complete line shall be true, straight and of uniform diameter.

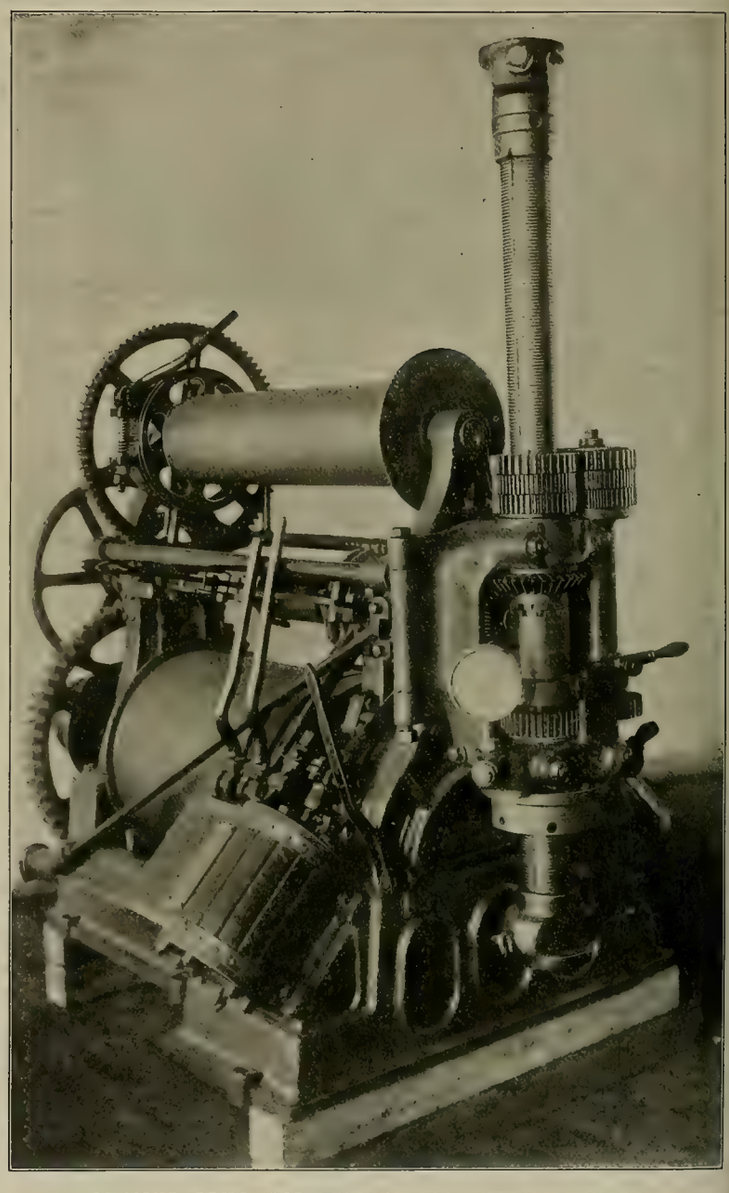
The water joint (Fig. 7) is the fitting which is screwed into the top of the line of rods and makes the water connection to the pump. It is a packing gland, the lower end finished with a drill rod thread, the upper end fitted with a nipple for the hose connection. A brass nut at the bottom affords means of adjustment to take up the wear of the packing.

The plain hoist plug (Fig. 8) is ordinarily used in hoisting and lowering the rods. The lower end is threaded to fit the upper end of the drill rod, and revolves freely upon the stem of the eye bolt, so that the hoisting rope is not untwisted when the plug is screwed into the rod.



In case of loose rock falling into the hole after the rods have been pulled to take out the core, and when "spudding" or driving pipe, it is necessary to keep a flow of water passing down the inside of the rods, while at the same time they are alternately raised and lowered or dropped quickly. To avoid delays and accidents, the combination water joint and hoist plug (Fig. 9) is used. From its name and the illustration, its use and construction will be understood.

The improved safety clamp (Fig. 10) is used for holding the rods while the operators are coupling or uncoupling the rods in hoisting or lowering.



When reaming out a hole preparatory to inserting a line of casing, the reaming bit being driven with a line of small rods, or when using a large core barrel and bit with small rods, there is frequently so much vibration that a high speed cannot be maintained. To overcome this, special guide couplings (Fig. 11) are used. The threaded part fits the drill rod thread and the body collar is made just large enough to fill the hole. These guide couplings are placed at intervals of 20 to 50 feet along the line of rods and are irregularly spaced, so that all of the distances between them can not correspond to the nodes of vibration.

Taps for recovering a line of rods lost in a hole are made in a great variety of forms. One shown in Fig. 12 is used when the upper end of the rods is not damaged, and is attached to the lower end of a line of rods, lowered, and tapped into the top of the lost rods. If the rods are broken and the upper end of those left in the hole are split, an "outside" tap is sometimes used. Frequently the top of the damaged rod must be cut off before the tap can be inserted. For this is used rose bits, either with an inside guide (Fig. 13), or with an "outside" or hog-nose guide (Fig. 14). The former is used when the top end of the rod is splintered but holds together, and the latter when the split end is spread apart. If the break is in the rod coupling and an outside tap or rose bit with an outside guide can not be used, a straight reamer (Fig. 15) is used for cutting away the part of the coupling remaining, so that the inside tap can be inserted. These taps are made in all sizes, and can be used for recovering casing, pipe and core barrels, the same as drill rods. The condition of the rod in the hole can be ascertained in case of breakage by a careful examination of the lower end of the recovered rod and by taking an impression of the rod in the hole by means of an impression cup filled with hard soap, tallow or wax; or if these are not available, very good results can be secured by using a soft wooden plug.

An effective and easily operated casing puller is a harpoon (Fig. 16). If the harpoon jaws encounter an obstruction while being lowered, they will slide up into the recessed chamber and lock in without injury to themselves or the possibility of their being caught

DIAMOND DRILL FOR GENERAL UNDERGROUND WORK.

DIAMOND DRILL FOR BORING DEEP VERTICAL HOLES.

in such a way as to prevent their removal from the hole.

For reaming below a line of casing to permit of driving it deeper, or for cutting off casing at any point when it has become fast in the hole, the hydraulic expanding reamer and cutter (Fig. 17) may be employed. It is fitted either with special tool steel jaws for cutting casing, or with blank jaws, to be set with diamonds. It is attached to a line of rods, lowered to the proper distance and the jaws expanded by water pressure transmitted through the rods. After its work has been accomplished the expanding jaws automatically return to place inside the barrel and the tool is raised to the surface.

Chopping bits used in driving pipe and "spudding" may be the single and double blade bits (Figs. 18 and 19). These are used in chopping through the surface ledges and ordinary wash or soil. The double blade bit works more rapidly than the single blade, but the latter is more easily annealed, dressed and tempered. The lipped bit (Fig. 20) and the auger (Fig. 21) are used in drilling through "hard pan," according to circumstances, and through clay a modified form of the auger (Fig. 22) is effective. The pod bit (Fig. 23) is used in going through loose sand or any heavy material that can not be handled by the clay auger. When a nest of gravel or small boulders is encountered, the double spiraled auger (Fig. 24) can be used to advantage, provided the boulders are not too large. In that case they must be chopped to pieces, or, if too hard, blown out with powder or dynamite.

Drive pipe should be carefully selected. It should be straight and true, free from blisters, and very strong, as great force is required in driving it. A heavy steel shoe (Fig. 25) of extra length should be used to prevent its turning over in the hole in case it becomes unscrewed. The drive head (Fig. 26) is threaded to receive a drill rod, which serves as a guide for the drive weight.

The jar collar (Fig. 27) screws into the top of the rod used as a guide, and is useful when the drive pipe or the drill rods have to be jarred up.

Clamps for holding drive pipe and casing are usually of the strap style (Fig. 28), although the hinged clamps are sometimes used where a large amount of pipe is to be handled. Casing is usually of a size just large enough to admit the passage of the regular boring tools. It is carefully straightened, cut to exact lengths and fitted with special inserted couplings, giving the whole line a uniform outside diameter.

After boring into rock a considerable distance it is sometimes found necessary to insert a line of casing to shut off quicksand or loose, caving ground. This can be done by reaming out the hole to the required size. The reaming bit, with guide, shown in Fig. 30, is generally used, but is subject to many modifications. A length of drill rod is sometimes substituted for the fluted front guide, and a piece of casing can be attached to the upper end of the bit to prevent any tendency to vibration. At best, the process of reaming out a hole for inserting casing is an expensive one, frequently costing as much as drilling the original hole, and where bad ground is known to exist, the wise course is to start the hole of a diameter large enough to allow the intertion of casing and continuing the work with the regular boring tools, after the caving ground has been drilled through and shut off by the casing line.

Prospect holes are located with reference to the extent of the property, what is known of the mineral and the development work which has been done. When possible, the holes should be located near a good supply of water, thus avoiding having to haul it. If water is scarce, provide a large settling tank, or sink barrels in the ground, draining the water from the drill hole, and using it over and over again.

When drilling, if large boulders or loose rock are encountered, a chopping bit is screwed to the lower end of the drill rod and this is raised and dropped, churn fashion, until the boulder or rock has been chopped up and the way is clear for driving the pipe.

As a general rule eight stones should be used for setting a diamond bit. Very large bits are frequently set with more stones, in order to "cover," and sometimes small bits are set with only six stones. It is poor economy to reduce first cost of the bit by cutting down the number of diamonds.

The diamonds should be picked out carefully, with especial attention to their location in the bit and a uniformity of size and weight. The latter point is important, for a small stone set with a number of large ones will become insecure in its setting and necessitate the resetting of the entire bit long before the balance of the stones require it. As a general rule, four of the strongest stones are picked out for the outside stones. These are placed in pairs, on lines at right angles; the lines joining the two pairs of inside stones bisect the angles of these lines. Laid out in this manner and carefully set, the bit will be well balanced and cannot but run smoothly and true.

On the opposite page are cuts of two types of diamond drills. The smaller is the type of machine used underground, and may be readily shifted from place to place. It can be adjusted to bore at any angle. The other is a large and powerful drill of the kind employed in sinking deep vertical holes. This machine is designed for cutting a hole to the depth of 3500 feet, and produces a core from 2 inches to 14 inches in diameter, according to tools employed.

The cost of diamond drill work is affected by various elements—the nature of the rock and overlying wash or soil, whether supplies can be obtained easily, the amount of drive pipe and casing, the necessity for a camp outfit, etc. In hard and badly broken formations the carbon cost will naturally be higher than in the softer strata, and in working in remote localities the items of traveling expense and transportation of machinery and supplies are considerable.

The Frozen Deposits of the North.

Written for the MINING AND SCIENTIFIC PRESS.

The correctness of the theory that the depth of unvarying temperature increases from 1 foot at the equator to 70 odd feet at the poles, has been called into question by a shaft having been sunk over 1500 feet in the sediments of northern Siberia without reaching the limit of frost and by the great depths to which frost extends in the Klondike. But while these facts are indisputable, they do not contradict the theory as much as they appear to at a first glance.

A further investigation of the facts of the case shows that in some localities where frost extends to great depths, there are places where the frost limit is reached in a few feet; that frost only extends to great depths in deposits which are either composed of sediments or the accumulations of a series of slides, while the places in which frost only extends to shallow depths are so situated that they can not be overlaid by surface deposits to any depth. Again, in consideration of the shallow depths to which ground is frozen by months of temperatures ranging from 10° to 60° below zero, the degree of cold necessary to freeze to the depth at which the search for the frost limit was abandoned in Siberia would leave an indelible imprint upon the rest of the earth, but thus far no such evidence has been discovered, as it would be a vastly greater degree than that requisite to produce any glacial epoch whose traces are discoverable at the present day. Furthermore, such a degree of cold would not freeze adjoining places to such varying depths when the rates of conductivity of their formations are practically identical.

The key to the solution lies in the fact that the localities in which the frost reaches depths much greater than those called for by the theory are situated in sections which are or were favorable for the accumulation of slides, sediments, etc., while the places in or near them situated unfavorably for such accumulation are only frozen to comparatively shallow depths. From this it is evident that instead of having been frozen to those immense depths by an intense degree of cold, the deposits were gradually frozen as they were formed. In other words, instead of having been frozen from the top down, they were frozen from the bottom up as they were formed by overlaying. In proof, then, that this process is still at work, and quiet and slow though it be in its operations, it is amply able to do all that has been done in that line of freezing without any unusual degree of cold.

At present the Klondike affords the best facilities for the study of the interesting phenomena attending the process of freezing from the bottom up. This is partly on account of the data furnished by the mining operations and partly because the easily decomposed schists of that section render the process more rapid than among harder formations. Although the process can be traced in all the valleys and low places, it is seen to the best advantage where the effacing hand of Nature is rebuilding, from the bottom up, the portions of the frozen deposits which have been mined out.

The process of freezing from the bottom up is practically as follows: The winter's freezing extends to a certain depth; the spring thaw, rains, etc., bring down the annual contribution of slides, sediments, etc., from the higher ground, before the ground is thawed very deep, and protects it by overlaying so that the summer's thaw fails to reach the limits of the winter's freeze. The cold of the ensuing winter usually freezes down to the old frost, but in cases where the season's accumulations are too great for that, they gradually become frozen by the excess cold surrounding them as the temperature of the frozen deposits is considerably below the freezing point.

On account of the great depths to which the vast alluvial plains and tundras of the north are frozen, they were evidently formed during a period of subsidence, when the sediments kept the surface near the water level while the underlying formation was sinking.

ASA THURSTON HEYDON, M. E.

NEVER in the history of railroading has there been such extensive improvements made by all the roads along their lines and in their equipment. All the Eastern lines are spending millions in improvements between New York and Chicago. The same can be said of the Western roads. It is estimated that the roads having terminals in Chicago contemplate making contracts, or they have already made them, that amount to about $10,000,000.

Concentration of Auriferous Sulphides in California.

NUMBER II —CONCLUDED.

Written for the MINING AND SCIENTIFIC PRESS.

Hydraulic separators are a great aid in concentrating auriferous slimes on canvas tables, though few of them are in use in California. There are a number of types of this useful contrivance. They are all built on the same principle, however. The pulp falls into a hopper-shaped box, with or without partitions, the coarse material going to the bottom and the fine slimes passing out at the top through a notch fitted with a launder. The size of the aperture at the bottom of the box is adjustable, so that the discharge of coarse material at that point may be regulated. In one of these hydraulic separators a perforated pipe is inserted to a point near the bottom and jets of clear water are forced into the mass of pulp, creating an upward current, causing the finer material to remain in suspension, thus more thoroughly effecting a complete separation of the slimes. This box is set below the vanners, which have already relieved the pulp coming from the batteries of the greater part of the sulphides contained in the ore, the material passing over the concentrator belts consisting essentially of coarse and fine sand and fine sulphides, a large part of which has been reduced to impalpable powder, and some of it so fine that on coming in contact with the air will float on water.

Passing through the separator, the coarse sand goes out at the bottom and flows away, waste, repeated tests having shown that it does not contain sufficient value to make further treatment profitable.

It would seem that this coarse sand, consisting almost entirely of grains of practically uniform size, might be discharged from the separator into a vat, allowed to drain and then be subjected to treatment by cyanide solutions at nominal expense, as the sands in most instances form an ideal material for treatment by that process. The fine material, passing out from the top of the pointed box, flows to the distributors at the head of the canvas plant.

The placing of a well constructed hydraulic sizer between the battery and the concentrating machines is certainly an idea worthy of consideration, but one not commonly practiced in California. By this means the pulp can be sized and the two grades thus formed can be sent to separate machines. The result is a cleaner product at no increased expense. In some cases carefully arranged hydraulic separators in competent hands may be made to perform such good work, in aiding properly adjusted concentrating machines, as to render further concentration on canvas tables useless. Such an arrangement would comprise two hydraulic separators and three concentrators. The pulp from the battery going to the first sizer effects a separation of the material into two grades, each grade going to a separate machine.

It will be found that the pulp has been relieved of the greater part of its sulphides by this first sizing and concentration. The pulp passing both machines should be collected and passed through the second sizer, so adjusted as to effect as closely as possible a separation of coarse and fine material, the latter going to the third and specially designed machine and the coarse sands to waste. In some ores, no doubt, values may still be found in the coarse material—this will be influenced largely by the method of crushing, whether stamps or rolls, and by the character of the ore, whether largely quartz or soft, talcose or chloritic material.

When an arrangement like that suggested above, or some modification of it, fails to accomplish the desired savings of slimes, the canvas table may be turned to as a last resort, but in many cases the canvas may be dispensed with by giving attention to sizing before concentrating on machines. It is unreasonable to expect a concentrating machine of any kind to save both coarse and fine material in a single operation, as that is contrary to natural laws, yet there are many who expect a clean and complete separation of both coarse and fine particles of heavy sulphides from a gangue of coarse and fine particles of relatively light material. When sizing by means of the separators has been first accomplished the particles are nearly of uniform size in each lot of the material and the difference of specific gravity of the various minerals then renders their separation much easier in the concentrators.

Canvas plants should be constructed, where possible, on a site affording abundant room, not only for the floor but for settling tanks, etc., and for possible extensions of plant which some change in the ore or addition to the mill may render necessary. Dry, seasoned lumber should be used. The posts must be provided with secure footing, as no sag must occur, any unevenness of the inclined surface destroying the usefulness of the plant. The floor should be made of narrow boards—3 or 4-inch material, planed on one side and on the edges. These should be laid with ½-inch space between them, as the swelling of the wood when water is turned on

will cause the boards to meet. If this precaution is not taken the floor will "buckle up" when wet. Pieces of flooring having knotholes should be rejected. The grade given plants is usually ½ to ¾-inch per foot. A small difference in grade does not materially effect the working of the plant, provided it be uniform. A box containing clear water must be placed across the head of the canvas sluices for the purpose of thinning the pulp, if necessary, and for washing down the tables, as explained in a former chapter. At some works the sweepings are conducted to a settling box having a partition 2 inches lower than the sides of the box. The sulphides, with much water, fall into this box. Naturally a large amount of the finer sulphides will remain in suspension in the water for some time and the greater amount of these pass over the partition, where, settling, they constitute a somewhat finer grade than those settling in the first compartment. The material settling in this compartment is removed and passed over a second concentrating machine of fine adjustment having a slight but rapid vibration. The tailings from this machine pass over a small auxiliary canvas floor, a further saving thus effected, the several products being almost wholly free from waste material.

The overflow from the settling box passes to a series of tanks, or rather to a large tank having numerous partitions, the water carrying sulphides in an extremely fine state of division, which, passing backward and forward from one compartment of the tank to the next, gradually settles on the bottom. These tanks do not need frequent cleaning, as it would require months to fill them, but the material is usually high grade — sometimes worth several thousand dollars per ton.

Nearly always a metallic, golden to bronze colored film may be found floating on the surface of the water in the tanks, concentrator boxes and settlers. This material is rich sulphide ore which, owing to its extreme fineness, is floating. Where this occurs it may usually be settled without difficulty by taking up the overflow of such box or tank and carrying it away through a pipe which discharges quietly into another box or vessel, the discharge end being beneath the surface of the water. It must be so arranged as to make as little current as possible, in order that the slimes may not rise again to con tact with the air, when they will again float, as before.

In tanks where the sulphide mineral remains in suspension, refusing to settle, it may usually be thrown down by the addition of lime to the water, which clarifies the liquid.

The sulphides obtained on canvas floors, being very fine, have given some trouble in treatment by the cyanide process, but a high extraction is usually possible by the agitation process, the solution being either drawn off by means of the vaccuum filter or by decantation. These fine sulphides often return a higher extraction than those taken from the concentrators. This fact is due to the difference in the size of the particles of material under treatment, the finer slimes rendering the microscopic particles of gold more easily accessible to the action of the solution of cyanide.

Cheap Mining and Milling at the Overland, Mercur, Utah.

Written for the MINING AND SCIENTIFIC PRESS.

On the Sunshine side of the Mercur district the Overland is the center of activity. The Overland

OVERLAND MILL, SUNSHINE, MERCUR DISTRICT, UTAH.

cyanide plant is treating 240 tons per day. The ore from this mine is favorable to this method of treatment, there being practically no talc or clay to hinder leaching and percolation. As an evidence of the thoroughness of the saving effected, I am informed that the tailings have been found to contain only from 30 to 40 cents per ton. In May the Overland mined and milled 2000 tons of ore at a cost of $1.92 per ton for mining and 81 cents per ton for milling. For the month of August 5500 tons were handled at a cost of $1.14 per ton for mining and 43½ cents per ton for milling, a total cost of mining and milling of $1.57½ per ton. Supt. G. A. Duncan and Metallurgist A. E. Smith have made special efforts to reduce the cost per ton as the tonnage handled increases, and the results are of general interest. Supt. Duncan expressed the belief that it would be mutually helpful if mining companies generally would accord publications like the MINING AND SCIENTIFIC PRESS more ready access to such figures as are here given. The Sunshine mine is under bond and lease to Gill S. Peyton and associates of the Overland, who are doing development work.

The Electrolytic Refining of Auriferous Silver.

Herr Dietzel, in a paper read before the German Electro-chemical Society, states that an instance of the most simple case of the electrolytic decomposition of alloys is as follows:

If the anode consist of silver containing gold, and an acid solution of silver nitrate is used as an electrolyte, silver is traveling to the cathode, and the same quantity is being added to the electrolyte at the anode; the gold remains at the anode and the electrolyte is not altered. Most of the practical cases in the electrolytic refining of metals are, however, much more complicated, as at the anode, besides one part of the anodic material dissolving, the other part is altered chemically, forming combinations with the elements of the electrolyte; in this case the electrolyte is also altered. If the combination formed at the anode is soluble in the electrolyte, the whole metallic concentration of the electrolyte is not altered, but the percentage of each of the metals is. The percentage of the metal deposited at the cathode decreases in the electrolyte and the percentage of the other metal increases, the sum of all the percentages being unchanged. If the anode is silver containing considerable copper, and if silver is intended to be deposited at the cathode, the silver percentage of the electrolyte decreases and the copper percentage increases to such a degree that it would soon be impossible to deposit pure silver at the cathode. If, therefore, a silver salt requiring a lower decomposition pressure is used as the electrolyte, the assistance of some auxiliary chemical process becomes necessary to diminish the increasing copper percentage and to increase the diminishing silver percentage in the electrolyte. Instead of this, it is much more convenient to use the salt requiring the higher decomposition pressure as the electrolyte, to deposit copper at the cathode and to replace the silver which is dissolved at the anode by an equivalent quantity of copper in a special process before the copper is deposited at the cathode. In this case the composition of the electrolyte remains nearly unaltered. This method has been successfully used for more than six years at Pforzheim, Germany, where about 60 kilograms of an alloy is decomposed per day. This alloy, consisting of fused wastes, contains 40% to 65% copper, 22% to 50% silver, 5% to 7% gold and small quantities of other metals. A slightly acid solution of copper nitrate is used as electrolyte. At the anode copper and silver are dissolved; copper is deposited at the cathode, the gold remains undissolved and the silver is recovered in another tank by special process, which is described. The current is about 150 amperes per square meter at 2½ to 3 volts. The cost of the process is covered by the value of the refined copper. He thinks that the same method can be used for decomposing other alloys, as, for instance, refining nickel and copper.—Electricity.

THE tides are now utilized for generating power at Pont l'Abbe, Finisterre, France, during fourteen hours per day. At flood tide the water flows through a canal two and one-half miles inland into a pond in the rear of the power house, and returns to the sea at ebb tide. The total fall is 7½ feet and 80 H. P. is generated by means of turbines. Means for applying this method of generating power to various industries have been considered. It seems rather singular, says an English contemporary, that practical means of harnessing the enormous energy of the tides have not been devised in numerous places where the rise and fall of water is equivalent to a head of from 25 to 30 feet and the volume of water available is, of course, only limited by the size of the reservoir constructed to receive it. Sometime ago there was much comment made in the London papers as to a proposal to utilize the tides at Southend.—Electricity.

THE mechanical uses of quicksilver are increasing and the electrical demand is so large that it is good opinion that the arts alone could consume all the quicksilver produced without any demand from the gold mining companies.

Horse Power Supplied at Niagara.

The amount of power drawn from Niagara Falls by the factories served by the Niagara Falls Co. is figured as follows:

	Horse Power.
International Paper Co.	7200
Pittsburg Reduction Co. (aluminum)	3050
Carborundum Co	1000
Buffalo & Niagara Falls Electric Light Co.	500
Electro-Chemical Co. (peroxide of sodium)	400
Buffalo & Niagara Falls Electric Railway	200
Niagara Falls & Suspension Bridge Railway	250
Buffalo & Lockport Electric Railway	350
Oldbury Electro-Chemical Co.	1000
Matheson Alkali Works	2000
Cataract Power & Conduit Co. (Buffalo)	8000
Tonawanda Power Co.	500
Union Carbide of Calcium Co.	10,000
Surface Coating Co. (enameling)	20
Niagara Development Co. (workingmen's dwellings)	75
Niagara waterworks	45
Total	34,590

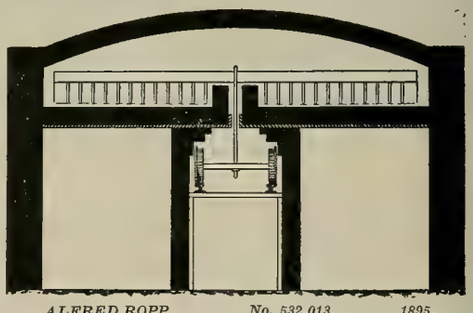
Next month, the Atchison Graphite Co. and the Lead Reduction Co. will be supplied, bringing up the total to 45,190 H. P. contracted for. The annual income is said to be $700,000 and the operating expenses $150,000 per annum.

The Furnace Controversy.

Regarding the present discussion concerning the Ropp furnace, the Brown furnace, etc., and Judge Hallett's recent ruling in a Colorado court, a pamphlet issued by the Parke & Lacy Co., San Francisco, says in part:

H. F. BROWN. No. 471,264. 1892.

"This drawing shows a section of the Brown furnace represented in the only Brown patent in controversy. In this patent Brown claims to have invented the improvement in ore furnaces consisting of a chamber at the side of the main roasting chamber, cut off from the main chamber by a wall or partition, in which the running gear of the rabbles is located."



* * * * *

R. GEORGE. No. 80,065. 1868.

"The construction of R. George's furnace is shown in the above drawing, copied from the records of the Patent Office."

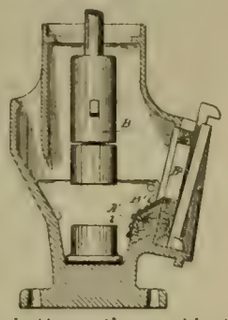
* * * * *

ALFRED ROPP. No. 532,013. 1895.

"The utter dissimilarity of the Ropp furnace from that of Brown is seen at once by comparing the drawings of the two furnaces."

* * * * *

"We are building the Ropp furnaces and we will continue to build them. We will stand between our customers, and secure them from any loss or damage from any action brought by Brown or others, based upon Brown's patent or patents."



A NOVEL use for the Roentgen rays is reported. It is stated that carbon in all its forms is transparent to these rays, while the incombustible constituents, silica and silicates, are opaque to them. By placing a lump of coal between a Crookes' tube and a fluorescent screen, the slag and ash forming parts of the fuel can be detected. In these tests rough lumps of coal up to 2 inches in thickness may be used with an exposure of five minutes and with a coil giving a 10-inch spark.
